

Northstar Retail Complete Manual Build Workbook

Learner: Kirolos Boules

Required platform path: Track A local-first batch architecture

Repository: <https://github.com/Losboules/SQL-Data-Warehouse-Project>

Workbook status: Instructional source of truth. No project execution is claimed.

Generated for use on: Windows

Current-source access date: August 16, 2026

How to use this workbook

This single Markdown file is the course, construction manual, exercise book, reference-answer book, validation guide, troubleshooting guide, Git guide, learning journal, progress tracker, and portfolio/interview guide. The project folders and files are created manually by you in your repository while following it. Code shown here is teaching material or an optional reference answer; it is not evidence that you typed, ran, tested, committed, or verified it.

Use one status only:

- ☐ Not started
- ☐ In progress
- ☒ Verified by me
- ☐ Needs troubleshooting

Also use these ownership labels:

- **PLANNED:** The workbook specifies the work.
- **CREATED BY USER:** You created the file/object but have not necessarily run or validated it.
- **RUN BY USER:** You executed it and preserved the actual result.
- **VERIFIED BY USER:** You independently inspected the required result and passed the gate.
- **NEEDS TROUBLESHOOTING:** The result differs or a gate failed.

Never change a status to verified because the reference answer looks correct. Complete the **MY TASK** section before opening the optional answer. Use hints in order: concept, pseudocode, then near-complete pattern.

Course-wide evidence rules

1. A screenshot proves only the visible state and filter/context shown.
2. A green test proves only the checks that actually ran against the data/configuration they actually read.
3. A Git commit proves the repository files existed at that snapshot; it does not prove a database or cloud object existed.
4. A database row count proves the selected table and filter returned that count; it does not prove upstream reconciliation.
5. A successful push proves commits reached the remote branch; it does not prove review, CI, or merge.
6. Never place passwords, tokens, connection strings, personal data, or account IDs in this workbook, screenshots, Git, logs, notebook output, or Power BI pages.

Major-concept three-level primer

Read this primer before the architecture walkthrough. Each concept is defined in plain language first, then tied to Northstar Retail, then stated in professional interview language. The first sentence under each concept is its definition; the everyday analogy follows immediately.

Source systems

Level 1 — Child-simple explanation

A **source system** is the place where information is first recorded while real work happens. It is like the original notebook where a cashier writes a sale before anyone makes a report about it.

Level 2 — Northstar Retail project explanation

Northstar uses SQL Server for ERP/store operations, PostgreSQL for web and marketing activity, and CSV/JSON files for partner-style feeds. These sources preserve operational business keys and events before the data is copied into analytical layers.

Level 3 — Professional explanation

Source systems are authoritative operational producers with their own schemas, transaction patterns, ownership, latency, and data-quality limits. The pipeline treats each source as a separate contract and does not redesign it merely for reporting convenience.

ETL and ELT

Level 1 — Child-simple explanation

ETL means extract, transform, then load; **ELT** means extract, load, then transform. ETL is like washing vegetables before placing them in the refrigerator; ELT is like storing them first and preparing them in the kitchen later.

Level 2 — Northstar Retail project explanation

Python extracts SQL Server, PostgreSQL, CSV, and JSON data into traceable batches. Databricks first lands raw evidence in Bronze and then transforms it into Silver and Gold, so the lakehouse portion follows an ELT-style pattern while local export preparation also performs controlled extraction work.

Level 3 — Professional explanation

ETL and ELT describe where transformation occurs relative to loading. Northstar uses a hybrid batch design: source-aware extraction and validation locally, immutable raw landing, and scalable transformation inside Databricks with auditable layer boundaries.

Medallion architecture

Level 1 — Child-simple explanation

A **medallion architecture** separates data into Bronze, Silver, and Gold levels. It is like keeping the original receipt, making a corrected copy, and then making a clean summary for the manager.

Level 2 — Northstar Retail project explanation

Bronze keeps source values and ingestion metadata, Silver applies cleaning and conformance rules while retaining rejected rows, and Gold creates dimensions, facts, and business-ready measures. Each layer has its own checks and rerun behavior.

Level 3 — Professional explanation

Medallion architecture is a layered lakehouse pattern that progressively increases trust and semantic structure. It separates raw lineage, conformed detail, and consumption-ready models so failures, schema changes, and reconciliations can be isolated at explicit contracts.

Data warehousing

Level 1 — Child-simple explanation

A **data warehouse** is a place arranged for answering questions about history rather than running the store minute by minute. It is like a well-organized record room instead of the cash register currently serving customers.

Level 2 — Northstar Retail project explanation

NorthstarRetail_DW receives verified Gold exports and stores staging tables, dimensions, facts, audit records, and analyst-facing views. Power BI reads this warehouse instead of joining the operational databases directly.

Level 3 — Professional explanation

Data warehousing creates a stable analytical boundary with historical integration, conformed definitions, dimensional structures, controlled loading, and repeatable reconciliation. It decouples reporting workloads and semantics from source-system transaction design.

Dimensional modeling

Level 1 — Child-simple explanation

Dimensional modeling puts measurable events in fact tables and descriptive labels in dimension tables. It is like keeping receipts in one box and customer, product, store, and calendar cards in labeled boxes around it.

Level 2 — Northstar Retail project explanation

Northstar creates nine dimensions and six facts. Sales, returns, inventory snapshots, shipments, web activity, and marketing spend each have a declared row meaning and connect to descriptive dimensions through warehouse-controlled keys.

Level 3 — Professional explanation

Dimensional modeling organizes analytical data around declared fact grains, conformed dimensions, surrogate-key relationships, additive behavior, and query-friendly star schemas. It makes business definitions explicit and supports predictable BI filtering.

Table grain

Level 1 — Child-simple explanation

Grain means exactly what one row represents. Saying “one row is one order item” is like saying every line on a receipt represents one purchased product, not the whole shopping trip.

Level 2 — Northstar Retail project explanation

fact_sales has one row per valid order item, while fact_inventory_snapshot has one row per product-store-snapshot date. Keys, duplicate tests, and measures are correct only when they match that declared grain.

Level 3 — Professional explanation

Table grain is the atomic business meaning of a row and must be declared before columns, keys, aggregations, or joins are designed. Grain drives uniqueness constraints, additive behavior, reconciliation logic, and late-arriving-key handling.

Surrogate keys

Level 1 — Child-simple explanation

A **surrogate key** is a warehouse-made identifier with no business meaning. It is like giving every library card a new internal number even when two outside systems use different customer numbers.

Level 2 — Northstar Retail project explanation

Gold dimensions assign integer keys to customer, product, store, employee, supplier, promotion, channel, campaign, and date rows. Facts store those keys so source identifiers can change or overlap without breaking warehouse relationships.

Level 3 — Professional explanation

Surrogate keys decouple analytical identity from mutable or heterogeneous natural keys. They support slowly changing history, compact fact relationships, unknown-member handling, and consistent integration across source systems.

SCD Type 2

Level 1 — Child-simple explanation

Slowly Changing Dimension Type 2 keeps an old version and adds a new version when a history-worthy description changes. It is like keeping both an old and a new address card with dates showing when each was valid.

Level 2 — Northstar Retail project explanation

Northstar uses SCD Type 2 for selected customer and product attributes. A changed record expires the prior current row, inserts a new effective-dated row, and lets facts resolve the version valid at the event time.

Level 3 — Professional explanation

SCD Type 2 preserves historical attribute truth through multiple surrogate-keyed versions per natural key, effective start/end timestamps, and a current-row indicator. Correct implementation requires change detection, non-overlapping validity windows, and idempotent reruns.

Incremental loading

Level 1 — Child-simple explanation

An **incremental load** processes only new or changed information after an accepted point. It is like reading only the pages added to a diary since the last bookmark instead of rereading the whole diary.

Level 2 — Northstar Retail project explanation

Northstar records a high-water mark and extracts rows after the last successful boundary, with a tie-breaking key where timestamps can repeat. The watermark advances only after the entire batch is accepted and audited.

Level 3 — Professional explanation

Incremental loading limits processing to a deterministic change range using source positions such as timestamps plus keys, change tracking, or CDC. It requires atomic watermark advancement, replay safety, late-data policy, and source-to-target reconciliation.

Idempotency

Level 1 — Child-simple explanation

Idempotency means repeating the same request does not create extra copies or a different final result. It is like pressing an elevator button twice without ordering two elevators.

Level 2 — Northstar Retail project explanation

A repeated Northstar batch ID is recognized through audit records, unique keys, Delta MERGE logic, or controlled replacement. The same accepted batch must not duplicate Bronze rows, dimension versions, facts, or warehouse loads.

Level 3 — Professional explanation

Idempotency is an operational guarantee that replaying the same logical input converges on the intended state. It depends on stable batch/event identifiers, deterministic transformations, transactional audit state, uniqueness rules, and explicit correction semantics.

Data-quality gates

Level 1 — Child-simple explanation

A **data-quality gate** is a check that must pass before data moves forward. It is like a door that stays locked when a package has the wrong label, missing pieces, or an unexplained count.

Level 2 — Northstar Retail project explanation

Northstar tests schema, nulls, keys, accepted/rejected counts, referential integrity, dimensions, fact grain, amounts, freshness, and source-to-target reconciliation. A blocking failure prevents Gold publication or downstream loading.

Level 3 — Professional explanation

Data-quality gates are executable acceptance criteria tied to business and technical risk. They record expected and actual values, severity, batch context, and evidence; blocking rules fail orchestration rather than merely producing a warning nobody reviews.

Orchestration

Level 1 — Child-simple explanation

Orchestration controls which jobs run first, which wait, and what happens after a failure. It is like a conductor telling different musicians when to start and stop.

Level 2 — Northstar Retail project explanation

A Databricks Lakeflow Job passes parameters, runs Bronze tasks, waits for dependencies, builds Silver and Gold, executes quality gates, and publishes only after required checks pass. Retry, timeout, repair, and notification behavior is documented.

Level 3 — Professional explanation

Orchestration coordinates task dependencies, execution context, parameters, retries, timeouts, schedules, observability, and failure propagation. A sound DAG makes data dependencies explicit and keeps repair runs consistent with idempotency rules.

Semantic models

Level 1 — Child-simple explanation

A **semantic model** gives data shared meanings, relationships, and calculations for reports. It is like a labeled map that tells everyone which roads connect and how distances are measured.

Level 2 — Northstar Retail project explanation

Power BI imports the warehouse tables, creates one-to-many relationships, uses a marked date table, hides technical keys, and defines measures such as Total Revenue, Gross Profit, Conversion Rate, and Return on Ad Spend.

Level 3 — Professional explanation

A semantic model is the governed analytical layer of entities, relationships, measures, formats, hierarchies, descriptions, and security consumed by reports. It centralizes business logic and filter behavior so visuals do not redefine metrics independently.

CI/CD

Level 1 — Child-simple explanation

CI/CD means automatically checking changes and, when appropriate, delivering approved changes through a repeatable process. It is like inspecting every part on a conveyor belt before allowing it into the next room.

Level 2 — Northstar Retail project explanation

GitHub Actions checks required files, Python tests, Markdown links, notebooks, SQL dialect expectations, and secret safety without pretending to run the learner's local databases or cloud workspace. Deployment remains limited to what is honestly automated.

Level 3 — Professional explanation

Continuous integration validates each proposed change in a clean runner, while continuous delivery/deployment promotes validated artifacts through controlled environments. Northstar's portfolio scope implements infrastructure-free CI and documents the boundary between repository validation and live-platform deployment.

Project architecture and ownership

Level 1 — Child-simple architecture

Northstar Retail has information in different boxes. SQL Server holds store/ERP records, PostgreSQL holds web/marketing records, and files bring returns, promotions, costs, and tracking events. Python copies each batch into labeled files. Databricks stores the raw copy in Bronze, cleans it in Silver, and arranges it for reporting in Gold. Verified Gold files are brought back to a local SQL Server warehouse. Power BI reads that warehouse and shows measures and report pages. GitHub stores the instructions and code, not the running databases.

Level 2 — One fictional order through every layer

A fictional customer places an online order. `erp.orders` records the order header and `erp.order_items` records each product line. PostgreSQL web tables record the session, campaign touchpoint, and conversion. Python extracts both sources into one batch with a batch ID, manifest, counts, and checksums. A human uploads that batch to a governed Databricks volume in Track A. Bronze preserves source values and file lineage. Silver parses dates, validates quantities/statuses, deduplicates business keys, and quarantines invalid records. Gold resolves dimension keys and writes one `fact_sales` row per valid order item. Quality gates reconcile counts and amounts. After a successful Job, verified Gold exports are downloaded and loaded into NorthstarRetail_DW. Power BI Import creates relationships and measures such as Total Revenue, Gross Profit, Conversion Rate, and Return on Ad Spend. GitHub records the code, tests, decisions, screenshots, and limitations.

Level 3 — Professional architecture walkthrough

The platform is a heterogeneous, batch-oriented, local-first portfolio implementation. SQL Server and PostgreSQL model normalized operational domains; structured file feeds model partner/operational handoffs. Deterministic Python workflows generate and load synthetic data, then create full and incremental extract batches with watermarks, manifests, checksums, and audit logs. Databricks implements a governed medallion architecture using Delta tables, parameterized notebooks, quality/reconciliation gates, and Lakeflow Jobs. Gold dimensions use surrogate keys and selected SCD Type 1/2 policies; Gold facts enforce declared grains and unknown-key behavior. Track A uses manual governed transfers because a remote workspace cannot automatically connect to a laptop's localhost. A local SQL Server dimensional warehouse provides a stable consumption boundary. Power BI uses Import, a star-schema semantic model, documented DAX, and SQL validation. GitHub Actions performs infrastructure-free repository checks, while live platform evidence remains separately verified.

What exists where

Location	Code/configuration	Data/objects	What it does not contain
Local repository	Python, SQL, YAML, Markdown, tests, workflow, Power BI requirements	Small fictional fixtures and verified screenshots only when appropriate	Running databases or Databricks tables
SQL Server source	T-SQL definitions are in Git	NorthstarRetail_ERP, erp tables, source audit data	PostgreSQL digital tables or Gold lakehouse tables
PostgreSQL source	PostgreSQL SQL definitions are in Git	northstar_digital, digital tables	SQL Server ERP tables
Local extraction folders	Python in Git controls the process	Batch files, manifest, checksum, watermark, logs	A cloud-accessible localhost endpoint
Databricks	Source notebooks/files can be Git-backed	Volume files, Bronze/Silver/Gold/quality Delta tables, Job runs	Automatic access to laptop loopback without networking
SQL Server warehouse	Warehouse DDL/loaders are in Git	NorthstarRetail_DW, staging, dimensions, facts, audits, views	Raw source-system behavior
Power BI Desktop	DAX and model requirements documented in Git	Local semantic model/report file and imported data	Source-of-truth raw data
GitHub	Versioned files and Actions logs	Commits, branches, PRs, issues, evidence images	Secrets, local databases, or unverified claims

Track A manual boundaries

1. Local extraction batch → manual upload to Databricks governed storage.
2. Verified Databricks Gold export → manual download to the local computer.
3. Local Python/SQL loader → SQL Server warehouse.
4. Power BI Import/refresh → local semantic model.

The manual steps are limitations to document, not gaps to hide.

Official and current source register

Installation screens, interface labels, account tiers, and product capabilities can change. The workbook uses the following official sources, accessed on **August 16, 2026**. Before clicking an installer or paying for a service, reopen the relevant official page and record any interface difference.

Official source	Used for	Accessed
Git for Windows	Installation and current Git package path.	August 16, 2026
Git switch	Branch creation and switching syntax.	August 16, 2026
GitHub: cloning a repository	HTTPS clone workflow.	August 16, 2026

Official source	Used for	Accessed
GitHub flow	Lightweight branch, commit, push, and pull-request workflow.	August 16, 2026
GitHub: ignoring files	.gitignore behavior.	August 16, 2026
GitHub: sensitive data	Credential-removal warning and recovery.	August 16, 2026
GitHub Actions quickstart	Actions UI and run-log navigation.	August 16, 2026
GitHub Actions concepts	Workflow, event, job, step, and runner definitions.	August 16, 2026
VS Code on Windows	User installer, PATH behavior, and code ..	August 16, 2026
VS Code Python tutorial	Interpreter selection and Python workflow.	August 16, 2026
Python on Windows	Official Windows installation guidance.	August 16, 2026
Python virtual environments	.venv creation and activation behavior.	August 16, 2026
SQL Server downloads	SQL Server 2025 Developer and Express download choices.	August 16, 2026
Install SSMS	SSMS 22 installer and Visual Studio Installer workflow.	August 16, 2026
Connect with SSMS	Connect dialog and query-window basics.	August 16, 2026
Microsoft ODBC Driver for SQL Server	Current ODBC driver downloads.	August 16, 2026
PostgreSQL Windows installers	Stable PostgreSQL installer, pgAdmin, and Stack-Builders.	August 16, 2026
PostgreSQL psql	Terminal client connection arguments and file execution.	August 16, 2026
pgAdmin connect to server	Server-tree connection behavior.	August 16, 2026
pgAdmin Query Tool	Query editor and output panes.	August 16, 2026
Databricks Free Edition limitations	Current serverless-only, quota, Jobs concurrency, language, networking, and account limitations.	August 16, 2026
Databricks notebooks	Current notebook experience.	August 16, 2026
Manage Databricks notebooks	Current create/open/clone paths.	August 16, 2026
Unity Catalog volume files	Catalog Explorer and notebook file-upload paths.	August 16, 2026
Configure Lakeflow Jobs	Jobs & Pipelines configuration.	August 16, 2026
Repair failed job runs	Repair-run workflow.	August 16, 2026
Delta Lake MERGE	Merge semantics used for idempotent updates.	August 16, 2026
Databricks secrets	Secret scopes and protected values.	August 16, 2026
Power BI Desktop download	64-bit Power BI Desktop and monthly updates.	August 16, 2026
Power Query SQL Server connector	Import versus DirectQuery and connection fields.	August 16, 2026
Power BI star schema	Fact and dimension modeling guidance.	August 16, 2026
Power BI relationships	Cardinality, filter direction, active/inactive relationships.	August 16, 2026
Power BI date tables	Date-table requirements.	August 16, 2026
Power BI drillthrough	Drill-through page behavior.	August 16, 2026
Power BI report tooltips	Tooltip configuration.	August 16, 2026

Current-version notes used in this workbook

- Microsoft's official download page offered SQL Server 2025 Developer for non-production development/testing and SQL Server 2025 Express on the access date.
- Microsoft's SSMS installation page described SSMS 22 through the Visual Studio Installer; the SSMS release notes identified 22.9.0, released August 11, 2026, as the current release on the access date.
- PostgreSQL's Windows page announced PostgreSQL 18.6 as a current stable release and PostgreSQL 19 Beta 3 as a development release on August 13, 2026; the beginner path uses a stable supported release rather than beta.
- pgAdmin documentation identified the current documentation stream as pgAdmin 4 version 9.17 on the access date.
- Python's current Windows documentation, published in the Python 3.14.7 documentation stream, emphasizes the Python Install Manager. Northstar deliberately pins the latest patched Python 3.13 runtime for project compatibility; record the exact patch you install.
- Power BI Desktop is 64-bit and updated monthly. Microsoft's official download page says only the latest version is supported, while the official archive's latest visible monthly section on the access date was June 2026; exact ribbon placement can therefore differ from examples.

- Databricks Free Edition documentation dated July 20, 2026 described serverless-only compute, quota limits, and a maximum of five concurrent Job tasks per account. Databricks notebook, volume, and Jobs interfaces still vary by cloud, workspace tier, permissions, and rollout, so the workbook gives a current primary path and a safe object-based fallback.
- The Microsoft ODBC Driver version available can change; record the exact installed driver name with Python/ODBC inspection and use that exact string.

Public repository observation before any write

On August 16, 2026, the public Losboules/SQL-Data-Warehouse-Project main-branch page displayed datasets/, docs/, scripts/, LICENSE, and README.md, with eight commits shown. Treat this only as a time-stamped observation. Phase 1 requires you to inspect the current remote and local clone yourself, preserve existing work, and avoid deleting or overwriting anything merely because this workbook saw a different state.

Windows path primer used throughout the workbook

The example repository path is C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. User is a placeholder and can differ on another computer. Never type a placeholder without finding your actual value.

- An **absolute path** begins with a drive such as C:\ and identifies a location from the drive root.
- A **relative path** is interpreted from the current folder. . means the current folder; .. means its parent; .\scripts means the scripts child of the current folder.
- A backslash separates Windows folder names. A space after C: is wrong because C: \Users is not C:\Users.
- Quotation marks are required when a path contains spaces and are safe around paths that do not contain spaces.
- \$HOME in PowerShell is your Windows home folder. Verify it with Write-Output \$HOME; do not assume it equals another person's path.
- Get-Location shows the current shell folder. git rev-parse --show-toplevel shows the repository root. These paths should agree when the action requires the root.
- Test-Path checks whether a path exists. Get-ChildItem shows what is inside it.
- SQL-Data-Warehouse-Project and SQL_Data_Warehouse_Project are different names. Missing or added hyphens do not refer to the same folder.

Path verification action

Action 1.P.1 — Verify the current Windows folder

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell or VS Code PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
Get-Location
```

Where to enter it:

Windows PowerShell or VS Code PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Location — Get-Location prints the current PowerShell folder

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.P.2 — Verify the Git repository root

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell or VS Code PowerShell terminal inside the clone

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

Windows PowerShell or VS Code PowerShell terminal inside the clone. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Phase 0 — Project orientation and the end-to-end mental model

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Nothing. This is the shared mental model.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 1 uses the architecture map to distinguish repository files from running systems.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 0 lesson index

1. [Lesson 0.1 — Understand the phase and starting screen](#)
2. [Lesson 0.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 0.3 — Create and understand the phase files](#)
4. [Lesson 0.4 — Build and validate required objects](#)
5. [Lesson 0.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 0.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Web browser, File Explorer, VS Code, and a paper or digital journal.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 0 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 0 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 0 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Web browser, File Explorer, VS Code, and a paper or digital journal. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 0 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 0 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 0 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 0.1 completion checklist

☐

I read why Phase 0 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 0.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 0 lesson index](#)

Lesson 0.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 0 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A mental map of the whole platform before you install or code anything. You will connect each unfamiliar word to one Northstar Retail example and write two architecture explanations: one simple enough to teach a child and one suitable for an interview.

2. Why it matters

Beginners often copy commands without knowing which system owns the data or why one step precedes another. Requirements precede source design; sources precede ingestion; raw data precedes cleaning; facts and dimensions precede semantic measures; tests precede publication. This phase gives every later action a place in that sequence.

3. Words to know

Term	Plain-language definition
Database	An organized system for storing and querying related data; SQL Server and PostgreSQL are separate database systems.
Data warehouse	A database designed for historical analysis, stable business definitions, and reporting.
Data lake	File-oriented storage that can retain raw and varied data.
Lakehouse	A lake with table reliability and warehouse-style management; this project uses Delta tables in Databricks.
ETL / ELT	Extract-transform-load versus extract-load-transform; the order tells you where transformation happens.
Pipeline	A repeatable path that moves and changes data through controlled steps.
Ingestion	Bringing source data into the platform.
Transformation	Changing type, structure, quality, or meaning under a documented rule.
Orchestration	Coordinating task order, parameters, retries, schedules, and failure handling.
Bronze / Silver / Gold	Raw evidence, trusted/conformed detail, and business-ready dimensions/facts.
Semantic layer	Shared relationships, measures, formats, and definitions used by reports.
Consumption layer	Where people query or view the data, such as Power BI or SQL.
Fact / dimension	A measurable event or snapshot, and the descriptive context around it.
Grain	Exactly what one row represents.
Primary / foreign key	A row identifier and a reference to another table's identifier.
Surrogate key	A warehouse-controlled key independent of a source business identifier.
Incremental loading	Processing new or changed records rather than rebuilding everything.
Data quality	Evidence that data is fit for a stated use.
Lineage	Evidence showing where a number came from and how it changed.

4. What must already be completed

Nothing. Begin with this workbook and inspect only repository files that already exist. Do not import, copy, or extract a prebuilt project.

5. Applications to open

Application	How to open it	Why it is open
Web browser	Open your normal browser from the Windows Start menu.	Read the public repository and official references.
File Explorer	Press Windows key + E.	Inspect the current repository and its visible folders without changing them.
VS Code or a text editor	Open it if already installed; otherwise use Notepad for this phase.	Read Markdown and write your first journal entry.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
Get-Date	Prints the current date and time.	Your journal and evidence need timestamps.
Get-Location	Shows the exact folder PowerShell currently considers active.	Folder awareness is the first defense against creating or deleting files in the wrong place.
Get-ChildItem README.md, docs\architecture.md	Confirms the three orientation files exist.	You should not proceed from an incomplete copy.

One-page architecture in plain language

The store system, website system, and files are separate boxes. Python makes safe practice data and copies one batch out. Databricks keeps the untouched batch in Bronze, makes a cleaned version in Silver, and organizes reporting tables in Gold. Tests act like a locked gate. After the gate opens, the local warehouse and Power BI use the trusted copy.

Interview version

Track A is a manifest-driven batch ELT architecture with heterogeneous local sources, a manual governed volume boundary, Delta medallion layers, SCD-aware dimensional Gold, a blocking quality gate, a SQL Server serving mirror, and a Power BI semantic model. The manual boundary is a deliberate low-cost networking constraint, not hidden automation.

MY TASK

Draw the platform as nine labeled boxes on paper or in your journal. Under each box, write who/what owns it, its input, its output, and one failure you would test.

STARTER SKELETON

TODO(USER) Simple explanation:
Northstar Retail starts with _____. Python then _____. Bronze keeps _____. Silver changes _____. Gold represents _____. The quality gate prevents _____. SQL Server DW serves _____. Power BI defines _____.

TODO(USER) Interview explanation:
This project uses a _____ batch architecture because _____. The declared grain of the main sales fact is _____. Trust is established with _____.

Acceptance criteria: Both explanations name the manual Track A boundary, distinguish Bronze/Silver/Gold, and explain why tests come before publication.

HINT 1 — CONCEPT

Think of Bronze as a sealed evidence bag, Silver as a cleaned workbench, and Gold as labeled reporting shelves.

HINT 2 — PSEUDOCODE

For each arrow, write: input → action → output → check.

HINT 3 — NEAR-COMPLETE PATTERN

Use the two sample explanations in docs/architecture.md only after attempting your own.

13. Expected files or output

- A journal entry dated today.
- Your own simple and professional explanations.
- A hand-drawn or text architecture with all required layers.
- No claim that any database or Databricks job has run.

14. How to verify

- You can state fact_sales grain without reading: one valid order item.
- You can explain why Power BI does not read the raw source directly in this design.
- You can explain why cloud Databricks cannot automatically reach your PC's localhost.

15. Automated tests

- Self-test: point to every architecture arrow and name the file/table produced.
- Quiz answers are checked only after writing them.
- No automated platform test is required in Phase 0.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
I keep mixing database, warehouse, and lakehouse	The words are new and overlap in normal conversation.	Open the architecture and identify where rows live at each stage.	Use one Northstar example per term; do not memorize dictionary definitions alone.	Explain each term using orders, not abstract words.
I think Bronze means bad data	Bronze means preserved source evidence, not worthless data.	Read the layer contract in docs/architecture.md.	Say 'raw with metadata' rather than 'bad'.	You can name why a raw copy is useful during a dispute.
I want to skip requirements and start SQL	Visible code feels like progress.	Open docs/business_requirements.md and choose one KPI.	Trace the KPI formula back to required source columns before coding.	You can state what source data would make the KPI impossible.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why does a pipeline need both a technical sequence and a business definition?
2. What does one row of fact_sales mean?

3. What is the difference between a source database and the serving warehouse?
4. What evidence would you need before saying a dashboard value is trusted?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which layer should preserve raw source values and source-file metadata?
2. Why is inventory snapshot quantity not safely additive across dates?
3. What is the purpose of a surrogate key?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture the overall architecture open in your browser beside your dated journal entry. This proves orientation work, not pipeline execution.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
docs: complete phase 00 architecture teach-back
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

I read both architecture explanations — [STATUS]

☐

I defined all required words using Northstar examples — [STATUS]

☐

I wrote my own two explanations — [STATUS]

☐

I understand the Track A manual boundary — [STATUS]

☐

I recorded no unverified result — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-0. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-0] (the answer-key section immediately after the quiz in this workbook#phase-0).

Next phase: Phase 1 safely inspects, clones, backs up, and expands the existing GitHub repository.

Required action cards

Action 0.2.0 — Inspect the workbook and any existing repository without importing a prebuilt project

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Inspect the workbook and any existing repository without importing a prebuilt project. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open this Markdown workbook in VS Code or a trusted Markdown viewer.
2. LOOK FOR: Confirm the filename is `Northstar_Retail_Complete_Manual_Build_Workbook.md`.
3. CLICK: Open File Explorer with Windows key+E.
4. LOOK FOR: Inspect whether a `SQL-Data-Warehouse-Project` folder already exists; do not create, extract, copy, delete, or overwrite anything yet.
5. If the folder exists, single-click it and record its full path from the address bar.
6. If the folder does not exist, record repository not cloned yet; Phase 1 teaches the clone action.
7. LOOK FOR: Keep this workbook as the only instructional source; old workbooks, exported notebooks, archives, or generated kits are not inputs to the manual-build path.
8. DO NOT CONTINUE UNTIL: You can state whether the repository already exists and where it is, without having changed it.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open this Markdown workbook in VS Code or a trusted Markdown viewer.
2. LOOK FOR: Confirm the filename is `Northstar_Retail_Complete_Manual_Build_Workbook.md`.
3. CLICK: Open File Explorer with Windows key+E.
4. LOOK FOR: Inspect whether a `SQL-Data-Warehouse-Project` folder already exists; do not create, extract, copy, delete, or overwrite anything yet.
5. If the folder exists, single-click it and record its full path from the address bar.
6. If the folder does not exist, record repository not cloned yet; Phase 1 teaches the clone action.
7. LOOK FOR: Keep this workbook as the only instructional source; old workbooks, exported notebooks, archives, or generated kits are not inputs to the manual-build path.
8. DO NOT CONTINUE UNTIL: You can state whether the repository already exists and where it is, without having changed it.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.2.1 — Open README.md and locate the business problem, architecture, and Track A boundary.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Open README.md and locate the business problem, architecture, and Track A boundary. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open README.md and locate the business problem, architecture, and Track A boundary.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 2

Action

Open README.md and locate the business problem, architecture, and Track A boundary.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.2.2 — Open docs/architecture.md. Read the child-simple explanation first, then the professional explanation.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Open docs/architecture.md. Read the child-simple explanation first, then the professional explanation. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open docs/architecture.md. Read the child-simple explanation first, then the professional explanation.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 3****Action**

Open docs/architecture.md. Read the child-simple explanation first, then the professional explanation.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.2.3 — Open docs/images/overall_architecture.svg in the browser. Trace one order from SQL Server to Power BI with y

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Open docs/images/overall_architecture.svg in the browser. Trace one order from SQL Server to Power BI with y. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open docs/images/overall_architecture.svg in the browser. Trace one order from SQL Server to Power BI with your finger or cursor.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 4

Action

Open docs/images/overall_architecture.svg in the browser. Trace one order from SQL Server to Power BI with your finger or cursor.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

[Back to the Phase 0 lesson index](#)

Action 0.2.4 — Open the complete glossary near the end of this workbook. Highlight only the terms that remain unclear; do n

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Open the complete glossary near the end of this workbook. Highlight only the terms that remain unclear; do n. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.

3. Perform only this immediate task: Open the complete glossary near the end of this workbook. Highlight only the terms that remain unclear; do not memorize everything at once.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 5****Action**

Open the complete glossary near the end of this workbook. Highlight only the terms that remain unclear; do not memorize everything at once.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Date
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Date — Get-Date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Location
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Location — Get-Location prints the current PowerShell folder

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 0.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 0 starting-screen checklist and re-verify the active context.

Lesson 0.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 0 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — docs/

Exact folder name: docs

Exact parent: repository root

Why it is needed now: Phase 0 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.

3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: docs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 0.D1.1 — Create the folder docs

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\docs" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\docs" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\docs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\docs" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — docs/architecture.md

Exact filename: architecture.md

Filename extension: .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: docs relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 0.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: architecture.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled architecture.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 0.F1.1 — Create the file docs/architecture.md from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.

6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\architecture.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\architecture.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs\architecture.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\docs\architecture.md" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/architecture.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under docs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/architecture.md`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\architecture.md"` and require True.
4. Run `git status --short -- "docs/architecture.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for docs/architecture.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: docs/architecture.md

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 0.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Architecture

## Child-simple explanation

Northstar Retail has information in three places: a store-and-order database, a website database, and files. A Python helper makes fictional practice data and later copies data out of the local databases. You manually place one sealed batch folder in Databricks because a cloud Databricks workspace cannot magically reach a database on your own computer. Databricks stores the original copy in Bronze, cleans it in Silver, and organizes it for reporting in Gold. After tests pass, you download Gold files and load them into a local SQL Server warehouse. Power BI reads that warehouse and shows definitions everyone can share.

![Overall architecture](images/overall_architecture.svg)

## Professional interview explanation

The default implementation is a batch ELT lakehouse pattern with three heterogeneous sources, deterministic synthetic fixtures, manifest-driven file handoff, Delta medallion layers, orchestrated validation gates, a dimensional Gold model, a mirrored SQL Server serving warehouse, and a Power BI semantic model. Track A intentionally uses manual upload/download boundaries to avoid false claims about private-network connectivity. Batch IDs, checksums, audit metadata, quarantine tables, effective-date joins, and idempotent replacement/merge patterns support traceability and safe reruns.

## Track A – local-first data flow

![Local-first flow](images/local_first_flow.svg)
```

Manual steps are honest parts of this learning track:

1. Upload the local extraction batch to a Unity Catalog volume.
2. Start the Lakeflow Job with that exact batch ID.
3. Download the validated Gold export.
4. Run the local SQL Server publication loader.
5. Refresh the imported Power BI model.

Track B – optional cloud-connected flow

![Cloud-connected flow](images/cloud_connected_flow.svg)

Track B replaces manual boundaries with network-accessible managed databases and cloud object storage. It requires real firewall/private networking decisions, supported JDBC drivers, secret management, least-privilege identities, and cost monitoring. It is not required to complete the beginner project.

Layer contract

Layer	Contract	Allowed changes	Rerun behavior
---	---	---	---
Bronze	Raw values plus source/batch/file/hash metadata	Parsing only enough to read; no business correction	Delete and replace same batch, or merge on batch/hash
Silver	Typed, standardized, deduplicated, conformed, valid and quarantined	Business-quality rules are explicit and tested	Batch replacement or Delta MERGE on business key/change hash
Gold	Dimensional facts/dimensions and governed aggregates	Surrogate keys, SCD, measures, unknown members	Deterministic keys and grain uniqueness prevent duplicates
Serving DW	Relational mirror for analysts/Power BI	Constraints, indexes, semantic views	Transactional stage-and-publish with audit records
Semantic/consumption	Shared definitions and report behavior	Measures, relationships, formatting, descriptions	Refresh only after validated publication

[Back to the Phase 0 lesson index](#)

What your screen should look like now

- Every Phase 0 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 0.3 completion checklist

`docs/architecture.md` was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 0.4](#) and recheck the root and branch.

Lesson 0.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 0.4.G1 — Inspect the current state without changing it

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.4.G2 — Create the smallest required object or decision

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Create the smallest required object or decision. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.4.G3 — Run the phase-specific verification

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run the phase-specific verification. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.4.G4 — Demonstrate one safe failure or alternate-result branch

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

Action 0.4.G5 — Record evidence and prepare the downstream handoff

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 0 lesson index](#)

What your screen should look like now

- The new Phase 0 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 0.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 0.5](#).

Lesson 0.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 0 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Local-first learning architecture

Question:

How should a beginner connect local databases, Databricks, a warehouse, and Power BI without inventing network connectivity?

Options considered:

- Track A with manual governed handoffs.
- Track B with cloud-accessible sources and automated connectivity.
- Skip Databricks and build only a local warehouse.

Beginner path selected:

Track A is required; Track B is optional.

Why this path was selected:

It exposes every boundary and lets the learner validate files, manifests, checksums, and tables without paying for a production network.

Tradeoff:

Manual upload/download adds latency and operational effort.

What a company might do instead:

Use private networking, cloud object storage, managed identities, service principals, and automated deployment.

How to explain this in an interview:

I chose a local-first batch path to make each boundary observable and reproducible; I documented the manual handoffs and did not claim that cloud Databricks could reach laptop localhost.

Design decision — Local versus cloud databases

Question:

Should the required beginner path run its source databases locally or pay for managed cloud databases?

Options considered:

- Local SQL Server and PostgreSQL with explicit manual cloud handoffs.
- Managed cloud source databases reachable by Databricks.
- A single all-cloud platform that removes the heterogeneous local boundary.

Beginner path selected:

Run the operational source databases locally and document the manual Track A transfer boundary.

Why this path was selected:

Local databases minimize cost, expose installation and connectivity fundamentals, and prevent the workbook from assuming cloud networking or paid services.

Tradeoff:

The laptop must be running for local work, collaboration is harder, and Databricks cannot directly reach loopback without real networking.

What a company might do instead:

Use managed databases, private networking, cloud object storage, managed identities, backups, monitoring, and infrastructure as code.

How to explain this in an interview:

I chose local source engines for cost-controlled learning and made the cloud handoff explicit; I would move to managed databases when availability, collaboration, security, and automated connectivity justify it.

If you see Result A

Your diagram names every system and manual boundary. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

One or more boxes/arrows are missing or ownership is unclear. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Web browser, File Explorer, VS Code, and a paper or digital journal.

Window/panel: Show the architecture map and dated learning-journal fields.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase00_project-orientation-and-the-end-to-end-mental-model_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 0's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 0 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 0.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.
- `MM` means a staged version exists and the file has additional unstaged edits.
- `A` means staged as a new file.
- `D` means deletion; stop and investigate unless deletion is deliberate.
- `R` means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 0.5.G4 — Inspect the unstaged diff for `docs/architecture.md`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "docs/architecture.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "docs/architecture.md"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"docs/architecture.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.5.G5 — Stage only the reviewed file docs/architecture.md

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "docs/architecture.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "docs/architecture.md"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"docs/architecture.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 0.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.5.G7 — Create the Phase 0 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "docs: record phase 00 architecture teach-back"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "docs: record phase 00 architecture teach-back"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"docs: record phase 00 architecture teach-back"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Action 0.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The orientation material in this workbook; no repository change is required yet.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The orientation material in this workbook; no repository change is required yet. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 0 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `docs: record phase 00 architecture teach-back` and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 0.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.

6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 0 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 0 created the verified boundary described by **Project orientation and the end-to-end mental model**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

Mini quiz

1. Multiple choice: Why does Phase 0 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 0.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 1 uses the architecture map to distinguish repository files from running systems.

Phase 0 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 1 — Repository inspection, preservation, branching, and preparation

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Phase 0 architecture and ownership rules.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 2 installs only the tools the inspected repository and planned architecture require.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 1 lesson index

1. [Lesson 1.1 — Understand the phase and starting screen](#)
2. [Lesson 1.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 1.3 — Create and understand the phase files](#)
4. [Lesson 1.4 — Build and validate required objects](#)
5. [Lesson 1.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 1.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Web browser, File Explorer, Windows PowerShell, VS Code, and GitHub.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 1 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 0 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 1 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Web browser, File Explorer, Windows PowerShell, VS Code, and GitHub. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 1 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 1 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 1 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 1.1 completion checklist

☐

I read why Phase 1 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 1.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 1 lesson index](#)

Lesson 1.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 1 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A safe local clone and feature branch that preserves the public repository's existing README, license, placeholder folders, and any local scripts/init_database.sql content before any manually created project structure is added.

2. Why it matters

Git gives you recoverable history, reviewable changes, and evidence of your own progress. The most dangerous beginner mistake here is not a complex merge—it is working in the wrong folder or overwriting existing work because two similar folder names are treated as identical.

3. Words to know

Term	Plain-language definition
Repository	A project folder whose changes Git tracks.
Clone	A local copy connected to a remote repository.
Remote	The GitHub copy, commonly named <code>origin</code> .
Branch	An independent line of changes.
Commit	A named snapshot of staged changes.
Stage	Select changes for the next commit.
Push	Send local commits to the remote.
Pull/rebase	Bring remote changes into local history.
Diff	A line-by-line view of changes.
Repository root	The top folder containing <code>.git</code> and README.
Explorer panel	VS Code's left-side file tree.
Source Control panel	VS Code view for Git changes and diffs.

4. What must already be completed

Phase 0 is complete. Git and VS Code may not be installed yet; if either command is missing, record the result and complete installation in Phase 2 before retrying.

5. Applications to open

Application	How to open it	Why it is open
Web browser	Open Start menu and your browser; navigate to the repository URL.	Inspect existing files and copy the clone URL.
Windows PowerShell	Right-click Start > Terminal/PowerShell, not an administrator window.	Navigate, clone, branch, and verify Git.
VS Code	Type <code>code .</code> after entering the clone, or open from Start.	Review Explorer and Source Control safely.

Application	How to open it	Why it is open
File Explorer	Press Windows key + E.	Cross-check actual folder names.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
Get-Location	Prints your current folder.	Every following relative path depends on this folder.
Get-ChildItem -Directory Select-Object Name	Lists exact child directory names only.	It prevents the earlier mistake of creating norths-tarretail-data-platform but entering northstar-retail-data-platform.
git clone https://github.com/Losboules/SQL-Data-Warehouse-Project.git	Creates a connected local folder named SQL-Data-Warehouse-Project.	The existing GitHub repository is the source baseline.
Set-Location .\SQL-Data-Warehouse-Project	Moves PowerShell into the cloned repository.	Git commands must target this project.
git rev-parse --show-toplevel	Asks Git for the true repository root.	Folder name alone does not prove you are inside a Git repository.
git status	Shows branch and changed/untracked files.	You need a clean baseline before migration.
git switch -c feature/northstar-platform	Creates and enters a new feature branch.	The manual project change should be reviewable and reversible without changing main immediately.
New-Item -ItemType Directory -Path scripts\legacy -ErrorAction Stop	Creates a safe legacy folder without deleting anything.	A surfaced legacy SQL file must be preserved before new SQL paths are added.
if (Test-Path scripts\init_database.sql) { Copy-Item scripts\init_database.sql scripts\legacy\init_database.original.sql -Force }	Copies the legacy SQL file only if it exists locally.	The repository inspection could not retrieve its content and therefore must not assume it is disposable.
code .	Opens this exact folder in VS Code.	Opening VS Code from the verified root avoids editing a look-alike folder.

Folder and file map before creation

Path	Purpose	First phase used
config/	non-secret scale, logging, and environment templates	5
datasets/	quick public sample; ignored raw batch folders	5-7
docs/	workbook, contracts, diagrams, evidence templates	all
notebooks/	GitHub showcase notebook and HTML	20
scripts/	Python/PowerShell generation, movement, validation	1 onward
sql/sqlserver/	T-SQL source, warehouse, validation, analytics	4, 15
sql/postgres/	PostgreSQL source and validation SQL	4
sql/databricks/	Spark SQL teaching patterns	9-13

Path	Purpose	First phase used
databricks/	runnable source notebooks and Job map	8-14
powerbi/	semantic model, DAX, page specification	16-17
tests/	unit/integration/quality/reconciliation tests	5 onward
.github/	CI and collaboration templates	19

the file-responsibility index in this workbook later names every individual file and its phase.

MY TASK

Clone the correct repository, create the feature branch, preserve any local legacy SQL file, create only the current phase files manually while preserving existing work, and write a one-paragraph migration note describing what existed before.

STARTER SKELETON

```
TODO(USER) Repository root: _____
TODO(USER) Existing branch before change: _____
TODO(USER) New branch: _____
TODO(USER) Files preserved: _____
TODO(USER) Files manually created or preserved and reviewed: _____
TODO(USER) Validation command/result: _____
```

Acceptance criteria: `git status` runs from the true root, the feature branch is active, existing work is preserved, and the first migration commit contains only understood changes.

HINT 1 — CONCEPT

A path is exact text: `northstarretail` is not `northstar-retail`.

HINT 2 — PSEUDOCODE

Ask Git for the root instead of trusting the prompt: `git rev-parse --show-toplevel`.

HINT 3 — NEAR-COMPLETE PATTERN

Use VS Code Source Control to open every changed README/SQL/config file before staging.

13. Expected files or output

- A local folder `SQL-Data-Warehouse-Project` connected to origin.
- Branch `feature/northstar-platform`.
- Preserved legacy copy if the file exists.
- The Phase 1 files you manually created or preserved are visible in Explorer.
- A clean validation result before commit.

14. How to verify

- `git remote -v` points to the correct public repository.
- `git branch --show-current` prints the feature branch.
- `git status --short` shows only intended migration changes before commit.
- `python -m scripts.validation.check_required_files` passes after Python setup in Phase 2.

15. Automated tests

- Manual root check with `git rev-parse`.
- File hash comparison for any preserved legacy SQL.
- Required-file CI script after dependencies are installed.
- GitHub diff review after push.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
Set-Location cannot find path	The typed child name differs from the one created or current parent is wrong.	Get-Location; Get-ChildItem -Directory \ Select Name.	Copy the exact returned name and use Set-Location '.\exact-name'.	Get-Location shows intended path.
fatal: not a git repository	PowerShell is outside the clone or inside a non-Git look-alike.	Get-ChildItem -Force; search for .git only in known project folders.	Return to the parent and enter the clone; do not run git init inside the wrong folder.	git rev-parse --show-top-level succeeds.
code is not recognized	VS Code PATH integration is missing or VS Code is not installed.	Get-Command code -Error-Action SilentlyContinue.	Complete Phase 2 VS Code install, reopen PowerShell, or use VS Code File > Open Folder.	VS Code opens the verified root.
Push rejected	Remote changed or wrong branch/upstream.	git branch --show-current; git fetch origin; git log --all --graph --oneline -15.	Review and rebase/pull the intended branch; never force-push main.	Remote feature branch shows commit.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. What is the difference between the GitHub repository name and any parent folder you create?
2. Why preserve scripts/init_database.sql even though the later project design introduces additional SQL files?
3. What does staging do that saving a file does not?
4. Why is the migration commit separated from later implementation work?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which command proves the true repository root?
2. Why should a beginner avoid working directly on main?
3. What should you do before overwriting an existing file?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture VS Code with the Explorer root, active feature branch, and Source Control changes visible. Do not include unrelated personal folders.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
chore: add northstar platform manual project structure while preserving baseline
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Correct repository URL inspected — [STATUS]

☐

Exact local folder verified — [STATUS]

☐

Feature branch active — [STATUS]

☐

Existing content backed up — [STATUS]

☐

Manual file diffs reviewed — [STATUS]

☐

Migration commit pushed — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-1. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-1] (the answer-key section immediately after the quiz in this workbook#phase-1).

Next phase: Phase 2 installs and verifies every required tool using current official guidance.

Required action cards

Action 1.2.0 — Inspect whether an earlier prebuilt archive was already imported without copying or deleting anything

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Inspect whether an earlier prebuilt archive was already imported without copying or deleting anything. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open the repository root in VS Code only after `git rev-parse --show-toplevel` confirms the path.
2. CLICK: Open the Source Control panel in the left Activity Bar.
3. LOOK FOR: Record every changed and untracked path before editing.
4. CLICK: Open Explorer and inspect whether folders such as `config`, `databricks`, `powerbi`, `sql`, or `tests` already exist.
5. TYPE THIS: `git status --short` in the VS Code PowerShell terminal.
6. PRESS: Enter.
7. TYPE THIS: `git ls-files`.
8. PRESS: Enter.
9. LOOK FOR: Distinguish tracked files from untracked files and compare them with the public repository baseline described in this phase.
10. DO NOT: Extract, copy, bulk-import, delete, or overwrite any prior archive contents.
11. Record whether an earlier starter archive appears to have been imported and list the evidence.
12. DO NOT CONTINUE UNTIL: The current state is preserved in `docs/repository_current_state.md` and no unexplained change has been made.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open the repository root in VS Code only after `git rev-parse --show-toplevel` confirms the path.
2. CLICK: Open the Source Control panel in the left Activity Bar.
3. LOOK FOR: Record every changed and untracked path before editing.
4. CLICK: Open Explorer and inspect whether folders such as `config`, `databricks`, `powerbi`, `sql`, or `tests` already exist.
5. TYPE THIS: `git status --short` in the VS Code PowerShell terminal.
6. PRESS: Enter.
7. TYPE THIS: `git ls-files`.
8. PRESS: Enter.
9. LOOK FOR: Distinguish tracked files from untracked files and compare them with the public repository baseline described in this phase.
10. DO NOT: Extract, copy, bulk-import, delete, or overwrite any prior archive contents.
11. Record whether an earlier starter archive appears to have been imported and list the evidence.
12. DO NOT CONTINUE UNTIL: The current state is preserved in `docs/repository_current_state.md` and no unexplained change has been made.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.0A — Adopt the manual-build rule for every new folder and file

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Adopt the manual-build rule for every new folder and file. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Keep the Phase 1 Explorer tree visible.
2. Read the folder and file tutorials in Lesson 1.3.
3. Create only the folder needed for the file currently being taught.
4. Create only one file at a time by the VS Code or PowerShell path in its file introduction.
5. Save the file.
6. Inspect its targeted Git diff.
7. Verify the file before creating the next one.
8. DO NOT: Use an archive, bulk copy, robocopy, Copy-Item from a prebuilt project, or a command that creates the whole future repository tree.
9. DO NOT CONTINUE UNTIL: You understand that the repository grows phase by phase through your own work.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Keep the Phase 1 Explorer tree visible.
2. Read the folder and file tutorials in Lesson 1.3.
3. Create only the folder needed for the file currently being taught.
4. Create only one file at a time by the VS Code or PowerShell path in its file introduction.
5. Save the file.
6. Inspect its targeted Git diff.
7. Verify the file before creating the next one.
8. DO NOT: Use an archive, bulk copy, robocopy, Copy-Item from a prebuilt project, or a command that creates the whole future repository tree.
9. DO NOT CONTINUE UNTIL: You understand that the repository grows phase by phase through your own work.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.1 — Open the correct GitHub page

Application:

Web browser on GitHub

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open the correct GitHub page. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Click the browser address bar.
2. Enter your repository address and press **Enter**.
3. Read the browser address carefully.
4. Confirm it contains both Losboules and SQL-Data-Warehouse-Project.
5. Scroll below the file list and read the current README.md before changing anything.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser on GitHub. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Expanded Step 1 — Open the correct GitHub page

Application: Chrome, Edge, or another web browser.

1. Click the browser address bar.
2. Enter your repository address and press **Enter**.
3. Read the browser address carefully.
4. Confirm it contains both Losboules and SQL-Data-Warehouse-Project.
5. Scroll below the file list and read the current README.md before changing anything.

Why: You are confirming that you are looking at your repository and learning what already exists.

Do not continue until: The address bar shows the correct owner and repository name.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.2 — Copy the HTTPS clone address

Application:

Web browser on GitHub

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Copy the HTTPS clone address. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Find the green **Code** button above the file list.
2. Click **Code**.
3. Make sure the **Local** tab is selected.
4. Select **HTTPS**.

5. Click the copy icon beside the displayed address.

Command or code:

```
https://github.com/Losboulos/SQL-Data-Warehouse-Project.git
```

Where to enter it:

Web browser on GitHub. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Expanded Step 2 — Copy the HTTPS clone address**

Application: Your web browser, still on the repository page.

1. Find the green **Code** button above the file list.
2. Click **Code**.
3. Make sure the **Local** tab is selected.
4. Select **HTTPS**.
5. Click the copy icon beside the displayed address.

The copied value should be:

Why: `git clone` needs the exact remote address.

Verification: Paste the address temporarily into Notepad, confirm it ends with `.git`, and then close Notepad without saving.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.3 — Open PowerShell and identify your current folder

Application:

Windows File Explorer

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open PowerShell and identify your current folder. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open PowerShell and identify your current folder
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

```
Get-Location
```

Where to enter it:

Windows File Explorer. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Expanded Step 3 — Open PowerShell and identify your current folder**

Application: Windows PowerShell. Do not use an administrator window.

Run:

Get-Location asks PowerShell, "Which folder am I currently inside?" The output may be C:\Users\User, C:\Users\User\Desktop, or another normal location.

Now move to the parent folder:

Verify:

Expected: The path ends with Northstar_Retail.

Common error: Cannot find path ... because it does not exist means one part of the path is spelled differently. Use File Explorer or `Get-ChildItem -Directory` to read the exact folder name instead of guessing.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.4 — Read the exact folder names before cloning

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Read the exact folder names before cloning. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Read the exact folder names before cloning
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

```
Get-ChildItem -Directory
```

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Expanded Step 4 — Read the exact folder names before cloning

Application: Windows PowerShell.

Current folder: C:\Users\User\Desktop\Northstar_Retail.

Run:

Read each name exactly. You may see the older folder you created, such as:

Leave that folder alone for now. The real cloned repository will be named:

Check whether it already exists:

- False means it is not present and you may clone.
- True means do not clone again; inspect the existing folder first.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.5 — Clone only when the repository folder does not exist

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Clone only when the repository folder does not exist. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Clone only when the repository folder does not exist
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

```
git clone https://github.com/Losboules/SQL-Data-Warehouse-Project.git
```

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Expanded Step 5 — Clone only when the repository folder does not exist**

Application: Windows PowerShell.

Current folder: C:\Users\User\Desktop\Northstar_Retail.

When Test-Path returned False, run:

What it does: Downloads the repository, its commit history, and the connection to GitHub. Git automatically creates SQL-Data-Warehouse-Project.

Expected: Messages beginning with Cloning into and ending without a red fatal error.

Common error:

This means the folder already exists. Do not delete it automatically. Enter it and verify whether it is the correct Git clone.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.6 — Enter the clone and prove that it is the repository root

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Enter the clone and prove that it is the repository root. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Enter the clone and prove that it is the repository root
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

```
Set-Location ".\SQL-Data-Warehouse-Project"
```

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Expanded Step 6 — Enter the clone and prove that it is the repository root

Run:

Check the Windows location:

Ask Git for the repository root:

Confirm the GitHub remote:

Expected: Both location commands point to SQL-Data-Warehouse-Project, and the remote contains Losboules/SQL-Data-Warehouse-Project.git.

Common error: fatal: not a git repository means you are standing in the parent folder or another unrelated folder.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.7 — Confirm a clean starting point and create a feature branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Confirm a clean starting point and create a feature branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Confirm a clean starting point and create a feature branch
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

```
git status
```

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Expanded Step 7 — Confirm a clean starting point and create a feature branch

Run:

Ideally, Git says:

Create and enter your work branch:

Verify:

Expected: feature/northstar-platform.

If Git says the branch already exists, use:

Why: main remains the stable original line while your large manual project change stays reviewable and reversible.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.8 — Open the correct folder in VS Code

Application:

Windows File Explorer

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open the correct folder in VS Code. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Open VS Code from the Start menu.
2. Select **File > Open Folder**.
3. Browse to C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project.
4. Click **Select Folder**.

Command or code:

```
code .
```

Where to enter it:

Windows File Explorer. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Expanded Step 8 — Open the correct folder in VS Code**

While PowerShell is inside the repository root, run:

The dot means “open the folder I am currently inside.”

If code is not recognized:

1. Open VS Code from the Start menu.
2. Select **File > Open Folder**.
3. Browse to C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project.
4. Click **Select Folder**.

In the **Explorer** panel, locate the existing README.md, LICENSE, datasets, docs, and scripts. In **Source Control**, make sure there are no unexplained changes before importing anything.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.9 — Preserve the existing SQL script

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Preserve the existing SQL script. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Preserve the existing SQL script
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

```
New-Item -ItemType Directory -Path ".\scripts\legacy" -ErrorAction Stop
```

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Expanded Step 9 — Preserve the existing SQL script

Application: VS Code integrated PowerShell terminal.

Current folder: Repository root.

Create the backup folder:

Confirm the original exists:

When the result is True, copy it:

Verify:

Why: New work should not silently erase an earlier file. The backup gives you a migration path and a clear history.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Action 1.2.10 — Open the public repository and read the current README before clicking anything. Confirm the URL contains `Los`

Application:

Windows File Explorer

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open the public repository and read the current README before clicking anything. Confirm the URL contains `Los`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open the public repository and read the current README before clicking anything. Confirm the URL contains Losboules/SQL-Data-Warehouse-Project.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows File Explorer. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Open the public repository and read the current README before clicking anything. Confirm the URL contains Losboulès/SQL-Data-Warehouse-Project.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.14 — Clone the repository. Do not first create another folder with a competing project name unless you intend it as

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Clone the repository. Do not first create another folder with a competing project name unless you intend it as. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Clone the repository. Do not first create another folder with a competing project name unless you intend it as the parent.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 5

Action

Clone the repository. Do not first create another folder with a competing project name unless you intend it as the parent.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.15 — Enter SQL-Data-Warehouse-Project, run `git rev-parse --show-toplevel`, and compare the returned path to ``Get`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Enter `SQL-Data-Warehouse-Project`, run `git rev-parse --show-toplevel`, and compare the returned path to ``Get`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Enter `SQL-Data-Warehouse-Project`, run `git rev-parse --show-toplevel`, and compare the returned path to `Get-Location`.
4. Pause while the application finishes the operation; do not click the same control twice.

5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 6****Action**

Enter SQL-Data-Warehouse-Project, run `git rev-parse --show-toplevel`, and compare the returned path to Get-Location.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.17 — Open VS Code with code .. In Explorer, locate README, LICENSE, datasets, docs, and scripts. In Source Contro

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open VS Code with code .. In Explorer, locate README, LICENSE, datasets, docs, and scripts. In Source Contro. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open VS Code with code .. In Explorer, locate README, LICENSE, datasets, docs, and scripts. In Source Control, confirm there are no unreviewed changes yet.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 8

Action

Open VS Code with code .. In Explorer, locate README, LICENSE, datasets, docs, and scripts. In Source Control, confirm there are no unreviewed changes yet.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

Action 1.2.18 — Before creating any new project file, create scripts/legacy; if scripts/init_database.sql exists, copy it

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Before creating any new project file, create scripts/legacy; if scripts/init_database.sql exists, copy it . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Before creating any new project file, create scripts/legacy; if scripts/init_database.sql exists, copy it there as init_database.original.sql.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 9****Action**

Before creating any new project file, create scripts/legacy; if scripts/init_database.sql exists, copy it there as init_database.original.sql.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#)

Action 1.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Location
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Location — Get-Location prints the current PowerShell folder

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-ChildItem -Directory | Select-Object Name
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `Get-ChildItem -Directory | Select-Object Name` — `Get-ChildItem` lists files and folders; `-Directory` is a command option or flag; its exact behavior is defined beside the command; `Select-Object` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.2.C3 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
git clone https://github.com/Losboules/SQL-Data-Warehouse-Project.git
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git clone https://github.com/Losboules/SQL-Data-Warehouse-Project.git` — `git` calls the Git version-control program; `clone` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `https` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `://` is a path, relative location, branch-style name, or file argument; verify every character before running it; `github.com` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `/` is a path, relative location, branch-style name, or file argument; verify every character before running it; `Losboules` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `/` is a path, relative location, branch-style name, or file argument; verify every character before running it; `SQL-Data-Warehouse-Project.git` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.2.C4 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Set-Location .\SQL-Data-Warehouse-Project
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Set-Location .\SQL-Data-Warehouse-Project — Set-Location changes the current PowerShell folder; . is a path, relative location, branch-style name, or file argument; verify every character before running it; SQL-Data-Warehouse-Project is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.2.C5 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
git rev-parse --show-toplevel
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Action 1.2.C10 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
code .
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `code` . — `code` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 1.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

I distinguished typed text from observed output — [STATUS]

I recorded differences caused by versions/tier — [STATUS]

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 1 starting-screen checklist and re-verify the active context.

Lesson 1.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 1 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — docs/

Exact folder name: docs

Exact parent: repository root

Why it is needed now: Phase 1 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: docs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 1.D1.1 — Create the folder docs

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\docs" -PathType Container` and require True.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\docs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\docs" -PathType Container`.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — README.md

Exact filename: README.md

Filename extension: .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: . relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 1.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in . one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.

6. CLICK: Select **New File**.
7. TYPE THIS: README.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled README.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 1.F1.1 — Create the file README.md from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\README.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\README.md" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\README.md" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\README.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- README.md`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.

5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under ..
2. Right-click the editor tab and choose **Copy Path**; compare the ending with README.md.
3. In PowerShell at the repository root, run Test-Path ".\README.md" and require True.
4. Run git status --short -- "README.md" to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for README.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: README.md

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 1.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Northstar Retail End-to-End Data Platform

> A beginner-owned, evidence-driven portfolio project for learning SQL Server, PostgreSQL, Python, Databricks, Delta Lake, dimensional modeling, Lakeflow Jobs, SQL Server warehousing, and Power BI.

**Original repository:** [https://github.com/Losboules/SQL-Data-Warehouse-Project](https://github.com/Losboules/SQL-Data-Warehouse-Project)
**Reference design assembled:** 2026-08-16
**Status:** This is an instructional reference. Kirolos must manually create, run, test, and verify each component before claiming it as completed.

## Business problem

Northstar Retail is a fictional omnichannel retailer. Leadership receives inconsistent answers because ERP sales/inventory, website behavior, marketing, shipments, returns, and supplier updates live in separate systems. This project creates a governed daily path from those sources to trusted dimensions, facts, KPIs, and a Power BI report.

## Architecture

(docs/images/overall_architecture.svg)

### Track A – default local-first path

1. Generate fictional source files with Python.
2. Load ERP data into local SQL Server and digital data into local PostgreSQL.
3. Extract timestamped Parquet/file batches with manifests and checksums.
4. Manually upload one batch folder to a Databricks Unity Catalog volume.
5. Run parameterized Bronze, Silver, Gold, quality, and publication tasks.
6. Download the validated Gold export.
7. Load it transactionally into local `NorthstarRetail_DW`.
8. Import the star schema into Power BI and validate every measure against SQL.

Databricks does not connect to the local machine's `localhost` in Track A. Manual upload/download steps are explicit learning boundaries.

### Track B – optional cloud-connected path

Use network-accessible managed SQL Server/Azure SQL and PostgreSQL, supported JDBC connections, controlled firewall/private networking, secret-managed identities, and cloud storage. This can incur database, compute, storage, egress, networking, and BI costs.

## Technology stack

| Area | Technology |
| --- | --- |
| Version control | Git, GitHub, GitHub Actions |
| Local development | Windows PowerShell, VS Code, Python 3.13.x |
| ERP source and serving warehouse | SQL Server + SSMS |
| Digital source | PostgreSQL + pgAdmin/psql |
| Lakehouse | Databricks, PySpark, Spark SQL, Delta Lake, Unity Catalog volumes |
| Orchestration | Databricks Lakeflow Jobs |
| Modeling | Bronze/Silver/Gold, star schema, SCD Type 1/2, unknown members |
| Semantic/consumption | Power BI and Databricks SQL views |
| Trust | pytest, SQL assertions, quality tables, manifests, checksums, reconciliation |

## Data sources

- SQL Server ERP: customers, addresses, products, categories, suppliers, stores, employees, orders, items, payments, shipments, inventory movements and snapshots.
- PostgreSQL digital: users, sessions, events, campaigns, touchpoints, and marketing spend.
- Files: returns CSV, supplier cost updates CSV, promotion calendar CSV, nested shipment tracking JSONL.
```

See [``docs/data_dictionary.md``](docs/data_dictionary.md) and [``docs/source_to_target_mapping.md``](docs/source_to_target_mapping.md).

Pipeline flow

`SQL Server ERP + PostgreSQL digital + CSV/JSON feeds → timestamped local extraction batch → Databricks Bronze → Silver → Gold → blocking quality gate → Gold export → NorthstarRetail\_DW → Power BI / analyst SQL.`

Track A deliberately uses manual upload and download boundaries; Track B replaces those boundaries with network-accessible sources and secured cloud storage.

Medallion layers

- **Bronze:** raw values, source file/system, ingestion timestamp, batch ID, and record hash.
- **Silver:** typed, trimmed, standardized, deduplicated, conformed, quality-flagged, and quarantined records.
- **Gold:** nine dimensions, six facts, SCD2 history for customer/product, unknown members, and governed aggregates/views.

Data model

![Gold star schema](docs/images/gold_star_schema.svg)

Every fact's grain is documented in the workbook and data dictionary. ``fact_sales`` is one valid order item. Inventory is a periodic snapshot and must not be summed across dates without a deliberate calculation.

Data-quality strategy

The generator intentionally creates controlled defects. Silver handles them with explicit rules and quarantine. Required tests cover not-null, uniqueness, accepted values, referential integrity, date/numeric ranges, freshness, schema drift, duplicate batches, source/layer reconciliation, SCD behavior, and revenue arithmetic. Publication depends on a passing quality gate.

Orchestration

![Lakeflow Jobs dependency](docs/images/jobs_dependency.svg)

The version-controlled example is [``databricks/jobs/job_definition.example.yml``](databricks/jobs/job_definition.example.yml). Every task path exists in ``databricks/notebooks/``.

Semantic model and dashboard

Power BI uses single-direction dimension-to-fact relationships, a marked date table, explicit measures, display folders, descriptions, and validation SQL. Report pages cover executive, sales, products, stores, customers, marketing, inventory, shipping/returns, and data quality. No ``pbix`` or result screenshot is fabricated.

How to run the project safely

1. Clone the existing repository

Run in **Windows PowerShell**, from the parent folder where you want the clone:

```
``powershell
git clone https://github.com/Losboules/SQL-Data-Warehouse-Project.git
```

```
Set-Location .\SQL-Data-Warehouse-Project
```

```
git switch -c feature/northstar-platform
```

2. Create Python environment

Run in **Windows PowerShell**, from the repository root:

```
py -3.13 -m venv .venv
```

```
Set-ExecutionPolicy -Scope Process -ExecutionPolicy Bypass
```

```
.\.venv\Scripts\Activate.ps1
```

```
python -m pip install --upgrade pip
```

```
python -m pip install -r requirements-dev.txt
```

3. Generate and validate quick data

```
python -m scripts.data_generation.generate_northstar_data --scale quick --seed 20260815 --output-dir datasets\sample
```

```
python -m scripts.validation.validate_generated_data --input-dir datasets\sample
```

4. Run local checks

```
python -m scripts.validation.check_required_files
python -m scripts.validation.validate_sql_dialects
python -m scripts.validation.validate_notebooks
python -m scripts.validation.scan_secrets
python -m scripts.validation.validate_markdown_links
python -m pytest -q
```

Follow the single manual-build workbook during construction. Keep this README limited to repository facts and evidence you have personally verified.

Repository structure

```
SQL-Data-Warehouse-Project/
├─ README.md, LICENSE, configuration and dependency files
├─ datasets/           # small sample, ignored raw batches, issue fixtures
├─ docs/              # workbook, phase chapters, diagrams, contracts, portfolio docs
├─ notebooks/         # GitHub showcase notebook and HTML
├─ scripts/           # setup, generation, extraction, loading, validation, utilities
├─ sql/              # dialect-separated SQL Server, PostgreSQL, Databricks SQL
├─ databricks/        # source notebooks and job definition
├─ powerbi/           # model, DAX, page requirements, screenshot checklist
├─ tests/             # unit, integration, data-quality, reconciliation
└─ .github/           # Actions, issue, and pull-request templates
```

During construction, use the file-responsibility index inside the manual-build workbook; do not create a separate file-manifest document.

Screenshots

Replace these placeholders with your own verified evidence:

- [ADD YOUR VERIFIED ROW COUNT]
- [ADD PHASE 4 SOURCE DATABASE SCREENSHOT]
- [ADD PHASE 14 JOB RUN SCREENSHOT]
- [ADD PHASE 15 WAREHOUSE RECONCILIATION SCREENSHOT]
- [ADD PHASE 16 POWER BI MODEL SCREENSHOT]
- [ADD PHASE 17 DASHBOARD SCREENSHOT]

Limitations

- Track A has manual cloud handoffs and daily batch latency.
- The sample and quick generator are reference material; record your own local test result before claiming verification. External-platform execution is not claimed.
- Beginner reporting assumes USD and simplified converting-session attribution.
- The Gold fact notebook reference includes a fact_sales teaching pattern and TODO(USER) ownership work for the remaining facts; optional answers appear only inside the manual-build workbook.
- The project is educational, not production certification.

Future improvements

See [docs/optional_extensions.md](#). Choose one only after the required checklist is personally verified.

What I learned

Replace this section after completion. Suggested prompts: How did grain prevent a mistake? Which failure did the quality gate catch? Why was SCD2 needed? What made a rerun safe? How did SQL and DAX validation differ?

```

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

```
<a id="phase-1-file-gitignore"></a>
### File introduction – `.gitignore`
```

```
**Exact filename:** `.gitignore`
**Filename extension:** `(no extension)`. In this project it identifies project text or configuration and helps the correct application choose syntax highlighting or execution behavior.
**Exact parent folder:** `.` relative to the repository root.
**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.
**What the file will contain:** project text or configuration for Phase 1.
**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.
**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.
**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.
**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.
```

VS Code click path

```
1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `.` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `.gitignore`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `.gitignore` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.
```

PowerShell path

```
<a id="action-1-f2-1"></a>
## Action 1.F2.1 – Create the file `.gitignore` from PowerShell
```

```
**Application:**
Windows PowerShell or the VS Code PowerShell terminal
```

```
**Window or panel:**
VS Code integrated PowerShell terminal opened at the repository root
```

```
**Starting condition:**
The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.
```

```
**Current folder or location:**
The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.
```

```
**What you are about to do:**
Run one explained PowerShell instruction and inspect its result before any next command is introduced.
```

```
**Why this action comes now:**
The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.
```

```
**Exact physical actions:**
```

```
1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches `The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.` or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.
```

```
**Command or code (PowerShell):**
```

```
```powershell  
New-Item -ItemType File -Path ".\.\.gitignore" -ErrorAction Stop
```

### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\.\.gitignore" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\.\.gitignore"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

### Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

### What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

### How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

## File-creation decision branches

### If the command creates the file

Run `Test-Path -LiteralPath ".\.\.gitignore" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

### If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- ".gitignore"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

### If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

## File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under `..`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `.gitignore`.
3. In PowerShell at the repository root, run `Test-Path ".\.\.gitignore"` and require `True`.
4. Run `git status --short -- ".gitignore"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for .gitignore

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** text

**Exact file:** `.gitignore`

**Purpose:** project text or configuration.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 1.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

## File introduction — docs/repository\_current\_state.md

**Exact filename:** repository\_current\_state.md

**Filename extension:** .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** docs relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** project documentation for Phase 1.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

## VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: repository\_current\_state.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled repository\_current\_state.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

## PowerShell path

### Action 1.F3.1 — Create the file docs/repository\_current\_state.md from PowerShell

---

#### Application:

Windows PowerShell or the VS Code PowerShell terminal

#### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

#### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

#### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

#### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

#### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

#### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

#### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\repository_current_state.md" -ErrorAction Stop
```

#### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

#### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

## What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\repository_current_state.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs\repository_current_state.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

## Does it change anything?

This can change files, Git state, packages, database objects, or data.

## Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

## What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

## Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

## What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

## How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

## Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

## Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

## Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

## What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

## How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

## File-creation decision branches

### If the command creates the file

Run `Test-Path -LiteralPath ".\docs\repository_current_state.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

### If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/repository_current_state.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

## If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

## File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under docs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/repository_current_state.md`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\repository_current_state.md"` and require `True`.
4. Run `git status --short -- "docs/repository_current_state.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for docs/repository\_current\_state.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** Markdown

**Exact file:** `docs/repository_current_state.md`

**Purpose:** project documentation.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 1.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
Inspected Repository State

Repository: https://github.com/Losboules/SQL-Data-Warehouse-Project
Reference inspection date: 2026-08-16

The public repository was inspected while this workbook was authored. Treat the observations below as a time-stamped reference only. You must inspect the current remote and your local clone yourself before changing anything.

Visible reference baseline

- Default branch displayed: `main`.
- Eight commits were visible at reference-inspection time.
- Root files displayed: `README.md` and an MIT `LICENSE`.
- Root folders displayed: `datasets/`, `docs/`, and `scripts/`.
- `datasets/` and `docs/` visibly contained placeholders.
- `scripts/` visibly listed `init_database.sql` and a placeholder.
- The visible README described a SQL Server data warehouse project.

Retrieval limitation

A directory listing can show that `scripts/init_database.sql` exists without proving its current contents. This workbook therefore does
not claim to know or replace that file. Inspect your clone first. When the file exists, preserve a reviewed copy as `scripts/legacy/
init_database.original.sql` before editing or relocating it.

Safe decision

Create new Northstar paths manually only when their phase introduces them. Use clearly separated paths such as `sql/sqlserver/source/` and
`sql/sqlserver/warehouse/`; do not overwrite a root-level legacy script. Begin with a feature branch, a written state record, and a targeted
backup of any file that will actually change.
```

## Line-by-line explanation

- **Line 1:** `# Inspected Repository State` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** blank line used only to separate logical sections for readability.

## File introduction — docs/repository\_migration\_plan.md

**Exact filename:** repository\_migration\_plan.md

**Filename extension:** .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** docs relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** project documentation for Phase 1.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

### VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: repository\_migration\_plan.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled repository\_migration\_plan.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

### PowerShell path

## Action 1.F4.1 — Create the file docs/repository\_migration\_plan.md from PowerShell

---

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\repository_migration_plan.md" -ErrorAction Stop
```

### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\repository_migration_plan.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs\repository_migration_plan.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

### Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

## What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

## How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

## File-creation decision branches

### If the command creates the file

Run `Test-Path -LiteralPath ".\docs\repository_migration_plan.md" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

### If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/repository_migration_plan.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

### If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

## File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under docs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/repository_migration_plan.md`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\repository_migration_plan.md"` and require True.
4. Run `git status --short -- "docs/repository_migration_plan.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for docs/repository\_migration\_plan.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** Markdown

**Exact file:** `docs/repository_migration_plan.md`

**Purpose:** project documentation.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 1.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
Safe Manual Preparation Plan for the Existing Repository
```

```
This plan protects the existing public and local repository while you build the project manually. It does not import, copy, or extract a prebuilt project.
```

1. Inspect the current GitHub repository in a browser and record the visible branch, folders, files, and commit count.
2. Locate an existing local clone or clone the repository into a normal parent folder such as ``C:\Users\User\Desktop\Northstar_Retail``.
3. Confirm the true repository root with ``git rev-parse --show-toplevel``.
4. Record ``git status``, ``git branch --show-current``, ``git remote -v``, and the latest commit before editing.
5. If uncommitted work exists, preserve it by committing understood changes on the correct branch or by creating a named patch/stash only after reviewing the diff.
6. Create or switch to ``feature/northstar-platform`` without deleting any existing branch.
7. If ``scripts/init_database.sql`` exists and later work may affect it, create ``scripts/legacy/`` manually and copy only that reviewed file to ``scripts/legacy/init_database.original.sql``.
8. Create ``docs/repository_current_state.md`` and ``docs/repository_migration_plan.md`` manually from the workbook lessons.
9. Create future folders and files only when their phase introduces them; never bulk-create the complete tree.
10. Review targeted diffs, stage only the intended Phase 1 files, commit the preparation work, and verify the branch on GitHub.

```
Suggested commit after you actually complete and verify these steps:
```

```
```text
docs: record repository baseline and manual build plan
```

If README.md needs later revision, preserve its original meaning in Git history and use VS Code diff before editing. Git history is the primary recovery mechanism; a backup copy is added only when the workbook explicitly teaches one for a file at risk.

Line-by-line explanation

```
- **Line 1:** `# Safe Manual Preparation Plan for the Existing Repository` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** blank line used only to separate logical sections for readability.
- **Line 3:** `This plan protects the existing public and local repository while you build the project manually. It does not import, copy, or extract a prebuilt project.` – `This` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `plan` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `protects` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `the` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `existing` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `public` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `and` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `local` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `repository` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `while` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `you` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `build` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 4:** blank line used only to separate logical sections for readability.

in the surrounding explanation; `build` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `plan` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 20:** ```` -
- **Line 21:** blank line used only to separate logical sections for readability.
- **Line 22:** `If` \README.md\ needs later revision, preserve its original meaning in Git history and use VS Code diff before editing. Git history is the primary recovery mechanism; a backup copy is added only when the workbook explicitly teaches one for a file at risk.` - `If` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `README.md` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `needs` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `later` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `revision` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `preserve` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `its` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `original` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `meaning` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `in` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Git` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

What your screen should look like now

- Every Phase 1 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 1.3 completion checklist

- [] `README.md` was created by me, saved, located correctly, and inspected – [STATUS]
- [] `.gitignore` was created by me, saved, located correctly, and inspected – [STATUS]
- [] `docs/repository\_current\_state.md` was created by me, saved, located correctly, and inspected – [STATUS]
- [] `docs/repository\_migration\_plan.md` was created by me, saved, located correctly, and inspected – [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 1.4] (#phase-1-lesson-4) and recheck the root and branch.

Lesson 1.4 – Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 1.4.G1 – Inspect the current state without changing it

Application:
Web browser

Window or panel:
Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:
The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:
The repository root `C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.

What you are about to do:
Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:
It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.

2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****Command or code:****

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

****Where to enter it:****
Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

****What each part means:****

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****What should happen:****
A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

****Expected example:****

> Your exact values may differ. The expected result is the same **type** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

****What may look different:****
Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

****How to verify success:****
Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

****Do not continue unless:****
You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

****Common mistake:****
Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

****Exact recovery:****
Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

****What you just accomplished:****
You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

****How this connects to the project:****
The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

Action 1.4.G2 – Create the smallest required object or decision

****Application:****
Visual Studio Code

****Window or panel:****
Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

****Starting condition:****
The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

****Current folder or location:****
The repository root `C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.

****What you are about to do:****
Create the smallest required object or decision. This is one bounded construction or inspection task.

****Why this action comes now:****
It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

****Exact physical actions:****

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****Command or code:****

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

****Where to enter it:****

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

****What each part means:****

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****What should happen:****

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

****Expected example:****

> Your exact values may differ. The expected result is the same **type** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

****What may look different:****

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

****How to verify success:****

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

****Do not continue unless:****

You can point to the visible result and explain what it proves. Mark the action ``VERIFIED BY USER`` only after that check.

****Common mistake:****

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

****Exact recovery:****

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

****What you just accomplished:****

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

****How this connects to the project:****

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

Action 1.4.G3 – Run the phase-specific verification

****Application:****

Web browser

****Window or panel:****

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

****Starting condition:****

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

****Current folder or location:****

The repository root ``C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project``. The ``User`` segment is an example; verify your real Windows username.

****What you are about to do:****

Run the phase-specific verification. This is one bounded construction or inspection task.

****Why this action comes now:****

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

****Exact physical actions:****

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****Command or code:****

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

****Where to enter it:****

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

****What each part means:****

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****What should happen:****

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

****Expected example:****

> Your exact values may differ. The expected result is the same **type** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

****What may look different:****

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

****How to verify success:****

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

****Do not continue unless:****

You can point to the visible result and explain what it proves. Mark the action ``VERIFIED BY USER`` only after that check.

****Common mistake:****

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

****Exact recovery:****

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

****What you just accomplished:****

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

****How this connects to the project:****

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

Action 1.4.G4 – Demonstrate one safe failure or alternate-result branch

****Application:****

Web browser

****Window or panel:****

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

****Starting condition:****

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

****Current folder or location:****

The repository root ``C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project``. The ``User`` segment is an example; verify your real Windows username.

****What you are about to do:****

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

****Why this action comes now:****

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

****Exact physical actions:****

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****Command or code:****

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

****Where to enter it:****

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

****What each part means:****

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****What should happen:****
A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

****Expected example:****

> Your exact values may differ. The expected result is the same **type** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

****What may look different:****
Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

****How to verify success:****
Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

****Do not continue unless:****
You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

****Common mistake:****
Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

****Exact recovery:****
Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

****What you just accomplished:****
You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

****How this connects to the project:****
The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

Action 1.4.G5 – Record evidence and prepare the downstream handoff

****Application:****
Web browser

****Window or panel:****
Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

****Starting condition:****
The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

****Current folder or location:****
The repository root `C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.

****What you are about to do:****
Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

****Why this action comes now:****
It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

****Exact physical actions:****

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****Command or code:****

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

****Where to enter it:****
Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

****What each part means:****

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

****What should happen:****
A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

****Expected example:****

> Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

****What may look different:****
Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

****How to verify success:****
Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

****Do not continue unless:****
You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

****Common mistake:****
Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

****Exact recovery:****
Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

****What you just accomplished:****
You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

****How this connects to the project:****
The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 1 lesson index](#phase-1-lesson-index)

What your screen should look like now

- The new Phase 1 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 1.4 completion checklist

- [] Every required object was built separately – [STATUS]
- [] Every object has a declared responsibility/grain – [STATUS]
- [] Inputs and outputs were inspected – [STATUS]
- [] A rerun or alternate-result branch was tested where applicable – [STATUS]
- [] Counts, keys, measures, relationships, or settings were independently validated – [STATUS]
- [] I can explain one failure and its safest recovery – [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 1.5](#phase-1-lesson-5).

Lesson 1.5 – Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 1 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision – Git branching strategy

****Question:****
How should project changes be isolated from the default branch?

****Options considered:****

- Commit directly to main.
- Use one feature branch for the guided build.
- Use many short-lived issue branches.

****Beginner path selected:****
Use a descriptive feature branch and targeted commits.

****Why this path was selected:****
It teaches branch isolation and review without imposing a complex team model on one learner.

****Tradeoff:****
A long-lived branch can drift from main.

****What a company might do instead:****
Teams often use short-lived branches, protected main, required reviews, and automated checks.

****How to explain this in an interview:****
I used a feature branch so my existing repository state remained recoverable, reviewed diffs before staging, and used targeted commits.

If you see Result A

`git status --short` is empty or shows only changes you intentionally documented. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

The repository contains existing modified or untracked files that must be preserved and explained. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

- [] Required files/objects exist in the exact location.
- [] I personally created or configured them.
- [] I ran the phase commands in the documented context.
- [] I inspected the output rather than relying on a green icon alone.
- [] Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.
- [] Same-batch/rerun behavior is known where applicable.
- [] A controlled failure or realistic alternate-result branch was tested safely where applicable.
- [] No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.
- [] Actual verified result: `[ENTER VERIFIED RESULT]`.

Point-of-failure troubleshooting record

Exact or representative error message:
`[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]`

What it means in plain language:
`[WRITE YOUR INTERPRETATION]`

Most likely cause:
`[WRITE ONE TESTABLE HYPOTHESIS]`

What not to do:
Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:
`[ENTER THE SMALLEST OBSERVATIONAL CHECK]`

How to read the diagnostic result:
`[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:
`[ENTER THE NARROW FIX]`

Alternative fix when applicable:
`[ENTER OR N/A]`

How to verify the fix:
`[ENTER THE INDEPENDENT RECHECK]`

How to return to the main tutorial:
Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Web browser, File Explorer, Windows PowerShell, VS Code, and GitHub.

Window/panel: Show GitHub file list, local branch/status, and preserved baseline evidence.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: `docs/images/phase01\_repository-inspection-preservation-branching-and-prepar\_verified.png`.

Recommended repository folder: `docs/images/`.

README placement: The section describing Phase 1's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

`[ADD YOUR VERIFIED SCREENSHOT HERE]`

Git checkpoint after the verified Phase 1 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use ****Save All****, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 1.5.G1 – Verify the repository root before Git operations

****Application:****

Windows PowerShell or the VS Code PowerShell terminal

****Window or panel:****

VS Code integrated PowerShell terminal

****Starting condition:****

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

****Current folder or location:****

The repository root `C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.

****What you are about to do:****

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

****Why this action comes now:****

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

****Exact physical actions:****

1. CLICK: Bring ****Windows PowerShell or the VS Code PowerShell terminal**** to the front.
2. LOOK FOR: Confirm the current location matches `The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.` or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press ****Enter**** for a one-line terminal command, ****F5/Execute**** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

****Command or code (PowerShell):****

```
``powershell
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.
- `MM` means a staged version exists and the file has additional unstaged edits.
- `A` means staged as a new file.
- `D` means deletion; stop and investigate unless deletion is deliberate.
- `R` means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 1.5.G4 — Inspect the unstaged diff for `README.md`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "README.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "README.md"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"README.md"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.5.G5 — Stage only the reviewed file README.md

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "README.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "README.md"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"README.md"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 1.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.5.G7 — Create the Phase 1 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "chore: preserve baseline and prepare feature branch"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "chore: preserve baseline and prepare feature branch"` — git calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"chore: preserve baseline and prepare feature branch"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Action 1.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 1 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message chore: preserve baseline and prepare feature branch and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 1.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 1 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 1 created the verified boundary described by **Repository inspection, preservation, branching, and preparation**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

Mini quiz

1. Multiple choice: Why does Phase 1 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.

5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** PLANNED, CREATED BY USER, and RUN BY USER describe earlier states; only inspected evidence supports verification.

What I can now explain without help:

[WRITE YOUR ANSWER]

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 1.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 2 installs only the tools the inspected repository and planned architecture require.

Phase 1 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 2 — Install and verify the Windows toolchain

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: A protected repository state from Phase 1.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 3 uses the verified editor and Git workflow to create requirements safely.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 2 lesson index

1. [Lesson 2.1 — Understand the phase and starting screen](#)
2. [Lesson 2.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 2.3 — Create and understand the phase files](#)
4. [Lesson 2.4 — Build and validate required objects](#)
5. [Lesson 2.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 2.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Web browser, Windows Settings, installers, PowerShell, VS Code, SSMS, pgAdmin, Databricks, and Power BI Desktop.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 2 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 1 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 2 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Web browser, Windows Settings, installers, PowerShell, VS Code, SSMS, pgAdmin, Databricks, and Power BI Desktop. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 2 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 2 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 2 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 2.1 completion checklist

☐

I read why Phase 2 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 2.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

Lesson 2.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 2 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A documented Windows development environment with Git/GitHub authentication, VS Code, Python 3.13 virtual environment, SQL Server and SSMS, PostgreSQL and pgAdmin/psql, ODBC driver, Power BI Desktop, and an available Databricks workspace option. Docker remains optional.

2. Why it matters

Tool installation is part of engineering because versions, drivers, authentication, services, and interpreters determine whether code can run. Recording the installed version and verification result makes later errors diagnosable instead of mysterious.

3. Words to know

Term	Plain-language definition
Installer	Program that adds software and often configures services or PATH.
PATH	Windows list of folders searched for commands.
Interpreter	The Python executable running your code.
Virtual environment	Project-specific Python packages isolated in <code>.venv</code> .
Database engine	Background service storing/querying data; SSMS/pgAdmin are client tools, not engines.
Instance	A named SQL Server engine installation, such as default or SQLEXPRESS.
Driver	Software allowing Python/BI/Spark to communicate with a database.
Authentication	How a system proves identity.
Extension	VS Code add-on for language/tool support.
Workspace	Databricks environment containing notebooks, data objects, compute, SQL, and Jobs.
Stable release	Supported production release, not preview/beta.
Quota	Usage limit that can stop or restrict free-tier work.

4. What must already be completed

Phase 1 clone/branch is prepared, and the verified repository state from Phase 1 is available. You have permission to install software on the Windows computer. If the computer is employer-managed, follow employer policy instead of bypassing controls.

5. Applications to open

Application	How to open it	Why it is open
Web browser	Open from Start.	Download only from official Git, GitHub, Microsoft, Python, PostgreSQL, pgAdmin, Databricks pages.
Windows PowerShell	Open a normal user session.	Run verification commands and create .venv.
Windows Settings / installers	Open downloaded signed installers.	Install local tools.
VS Code	Open after install.	Add extensions and select interpreter.
SSMS / pgAdmin / Power BI	Open each from Start after installation.	Verify first launch and record version.
Databricks browser workspace	Sign in to an available account/workspace.	Confirm tier-specific capabilities before relying on them.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
git --version	Prints the Git command version.	Confirms install and PATH.
code --version	Prints VS Code version/build information.	Confirms command-line launch is available.
py -3.13 --version	Uses the Windows Python launcher to select Python 3.13.	Avoids accidentally creating .venv with another interpreter.
py -3.13 -m venv .venv	Creates an isolated interpreter and package folder.	Project dependencies should not modify global Python.
Set-ExecutionPolicy -Scope Process -ExecutionPolicy Bypass	Allows scripts only in this PowerShell process.	Activation can be blocked by policy; process scope avoids a permanent machine change.
..\env\Scripts\Activate.ps1	Places .venv Python first for this terminal.	All package installs and scripts must use the project interpreter.
python -m pip install --upgrade pip	Updates pip inside .venv.	Reduces packaging issues before dependency install.
python -m pip install -r requirements-dev.txt	Installs runtime and development dependencies from version constraints.	The generator, tests, notebook export, and validation scripts need them.
psql --version	Prints PostgreSQL command-line client version.	Confirms CLI availability independently of pgAdmin.
python -c "import pyodbc; print(pyodbc.drivers())"	Lists installed ODBC driver display names.	.env must use the exact SQL Server driver name.
.\scripts\setup\verify_local_tools.ps1	Runs grouped non-destructive CLI checks.	Creates one final tool availability snapshot.

Current version guidance (verified 2026-08-16)

Tool	Guidance	Avoid
Git / VS Code	Current stable official Windows release	third-party download sites
Python	Latest patched 3.13.x for project compatibility	beta/preview or unsupported EOL release

Tool	Guidance	Avoid
SQL Server	SQL Server 2025 Developer (non-production) or Express	treating Developer as production license
SSMS	Current SSMS 22	assuming SSMS installs the engine
ODBC	Microsoft ODBC Driver 18 current patch	guessing driver string
PostgreSQL	Current stable PostgreSQL 18.x	PostgreSQL 19 beta for this beginner project
Power BI	Current Desktop from Microsoft Store/official source	multiple unmanaged installs
Databricks	Available workspace; verify Free Edition limits	assuming paid features or unlimited compute

Exact point releases can change. Record what you installed and keep links in the `official source` register near the beginning of this workbook.

MY TASK

Install/verify each required tool, record exact versions and SQL Server/PostgreSQL instance/port choices without secrets, create `.venv`, install dependencies, and select the correct VS Code interpreter.

STARTER SKELETON

```
TODO(USER) Tool inventory
Git: version _____ / verification _____
VS Code: version _____ / interpreter path _____
Python: version _____
SQL Server: edition _____ / instance _____ / auth _____
SSMS: version _____
ODBC driver exact name: _____
PostgreSQL: version _____ / port _____ / service _____
pgAdmin: version _____
Power BI Desktop: version _____
Databricks: workspace type/tier _____ / limitations reviewed _____
Docker (optional): not used / reason _____
```

Acceptance criteria: All required verification commands succeed, GUI tools launch, the selected interpreter is `.venv`, and no credential appears in tracked files or the journal.

HINT 1 — CONCEPT

The database engine is a service; SSMS and pgAdmin are windows used to talk to engines.

HINT 2 — PSEUDOCODE

When import fails, compare `python -m pip --version` and `sys.executable` before reinstalling.

HINT 3 — NEAR-COMPLETE PATTERN

Use the `official source` register near the beginning of this workbook as a checklist and record the installed version beside each source.

13. Expected files or output

- `.venv/` exists locally and is ignored by Git.
- Dependencies installed into `.venv`.
- Tool/version inventory in the journal.
- SQL Server instance name and PostgreSQL port recorded without passwords.
- Databricks tier/limitations recorded.
- No duplicate Python or Power BI install confusion left unresolved.

14. How to verify

- `git --version`, `code --version`, `py -3.13 --version`, and `psql --version` work.
- `Python import` command succeeds.

- SSMS opens and shows Connect dialog.
- pgAdmin opens and prompts for master password/server connection as applicable.
- Power BI Desktop opens to Home.
- Databricks workspace opens and current capability/limit pages have been read.

15. Automated tests

- Run `python -m pytest -q tests/unit/test_generator.py` after sample generation later; dependency import is enough now.
- Run secret scan to ensure setup notes contain no credential: `python -m scripts.validation.scan_secrets`.
- Run `git check-ignore .venv .env`; both should be ignored once `.env` exists.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
Command not recognized	Installer did not add PATH or current terminal predates install.	<code>Get-Command <name> -ErrorAction SilentlyContinue</code> .	Restart terminal; verify official install options; use full path temporarily rather than random PATH edits.	Version command succeeds.
Activation is disabled	PowerShell policy blocks scripts.	<code>Get-ExecutionPolicy -List</code> .	Use process-scope Bypass only, then activate.	Prompt shows <code>.venv</code> .
Wrong Python in VS Code	Global interpreter selected.	VS Code terminal: <code>python -c "import sys; print(sys.executable)"</code> .	Select Interpreter and reopen terminal.	Path ends <code>.venv\Scripts\python.exe</code> .
ODBC driver absent	Driver installer not run or architecture mismatch.	Python pyodbc driver list.	Install current official 64-bit Microsoft ODBC driver and restart apps.	Exact driver appears.
Databricks menu differs	Workspace cloud, tier, rollout, or UI changed.	Check workspace/account type and current official page.	Use the equivalent current object; record variance; do not claim unavailable feature.	Environment check later uses accessible resources.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why is SSMS not the SQL Server database engine?
2. Why use `.venv` and `python -m pip`?
3. What is the difference between an instance name and a database name?
4. Why must Databricks feature/tier assumptions be verified from current documentation?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which Python version line should create this project's `.venv`?
2. What command lists exact installed ODBC driver names?
3. Why is process-scope execution policy safer than changing machine scope for this task?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture a four-panel evidence set: PowerShell version checks, VS Code interpreter path, SSMS Connect dialog, and pgAdmin server tree. Never expose passwords.

Save the image under `docs/images/` with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Official sources used — [STATUS]

☐

Git/GitHub auth verified — [STATUS]

☐

VS Code/extensions/interpreter verified — [STATUS]

☐

Python .venv and packages verified — [STATUS]

☐

SQL Server + SSMS + ODBC verified — [STATUS]

☐

PostgreSQL + pgAdmin/psql verified — [STATUS]

☐

Power BI verified — [STATUS]

☐

Databricks option and limitations verified — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-2. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-2.

Next phase: Phase 3 turns the business problem into testable requirements before source schemas are built.

Required action cards

Action 2.2.1 — Open the official source register near the beginning of this workbook. Use only its official domains as the

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open the official source register near the beginning of this workbook. Use only its official domains as the . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.

2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open the official source register near the beginning of this workbook. Use only its official domains as the primary installation authority. The access date is 2026-08-16; verify the current stable release shown when you install.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 1****Action**

Open the official source register near the beginning of this workbook. Use only its official domains as the primary installation authority. The access date is 2026-08-16; verify the current stable release shown when you install.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.2.2 — Install Git for Windows. Keep the recommended Git Credential Manager option and normal HTTPS behavior. Avoid c

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Install Git for Windows. Keep the recommended Git Credential Manager option and normal HTTPS behavior. Avoid c. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Install Git for Windows. Keep the recommended Git Credential Manager option and normal HTTPS behavior. Avoid changing line-ending or shell options you do not understand; record choices.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 2

Action

Install Git for Windows. Keep the recommended Git Credential Manager option and normal HTTPS behavior. Avoid changing line-ending or shell options you do not understand; record choices.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Action 2.2.3 — Authenticate to GitHub through the browser/device flow prompted by Git Credential Manager on the first protect

Application:

Web browser on GitHub

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Authenticate to GitHub through the browser/device flow prompted by Git Credential Manager on the first protect. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Authenticate to GitHub through the browser/device flow prompted by Git Credential Manager on the first protected operation. GitHub account passwords are not used as raw Git passwords.
4. Pause while the application finishes the operation; do not click the same control twice.

5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser on GitHub. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 3****Action**

Authenticate to GitHub through the browser/device flow prompted by Git Credential Manager on the first protected operation. GitHub account passwords are not used as raw Git passwords.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.2.9 — Install the current Microsoft ODBC Driver 18 for SQL Server. Record the exact driver name Python reports.

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Install the current Microsoft ODBC Driver 18 for SQL Server. Record the exact driver name Python reports. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Install the current Microsoft ODBC Driver 18 for SQL Server. Record the exact driver name Python reports.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 9

Action

Install the current Microsoft ODBC Driver 18 for SQL Server. Record the exact driver name Python reports.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.2.10 — Install the current stable PostgreSQL 18.x Windows package. Record the port (commonly 5432), superuser name, p

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Install the current stable PostgreSQL 18.x Windows package. Record the port (commonly 5432), superuser name, p. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Install the current stable PostgreSQL 18.x Windows package. Record the port (commonly 5432), superuser name, password location (not in Git), and service name. Include pgAdmin and command-line tools.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL `psql`, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 10****Action**

Install the current stable PostgreSQL 18.x Windows package. Record the port (commonly 5432), superuser name, password location (not in Git), and service name. Include pgAdmin and command-line tools.

Before continuing☐

I used the application named in this phase.

Action 2.2.11 — Install Power BI Desktop from the Microsoft Store where allowed for update management; otherwise use Microsoft

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Install Power BI Desktop from the Microsoft Store where allowed for update management; otherwise use Microsoft. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Install Power BI Desktop from the Microsoft Store where allowed for update management; otherwise use Microsoft's official download center. Do not install both paths without a reason.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 11

Action

Install Power BI Desktop from the Microsoft Store where allowed for update management; otherwise use Microsoft's official download center. Do not install both paths without a reason.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

Action 2.2.16 — Optional Docker path: use only after the native path works or when you can explain ports, volumes, container p

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Optional Docker path: use only after the native path works or when you can explain ports, volumes, container p. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Optional Docker path: use only after the native path works or when you can explain ports, volumes, container persistence, licensing, and Windows virtualization. Docker is not required for Track A.
4. Pause while the application finishes the operation; do not click the same control twice.

5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 16****Action**

Optional Docker path: use only after the native path works or when you can explain ports, volumes, container persistence, licensing, and Windows virtualization. Docker is not required for Track A.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
git --version
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git --version` — `git` calls the Git version-control program; `--version` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
code --version
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `code --version` — `code` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--version` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m pip install --upgrade pip
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m pip install --upgrade pip` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `pip` the Python package installer module; `install` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--upgrade` is a command option or flag; its exact behavior is defined beside the command; `pip` the Python package installer module

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m pip install -r requirements-dev.txt
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m pip install -r requirements-dev.txt` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `pip` the Python package installer module; `install` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-r` is a command option or flag; its exact behavior is defined beside the command; `requirements-dev.txt` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.2.C9 — Windows PowerShell

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
psql --version
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** psql --version — psql is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; --version is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.2.C10 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -c "import pyodbc; print(pyodbc.drivers())"
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -c "import pyodbc; print(pyodbc.drivers())"` — python invokes Python when that command name is registered; `-c` creates the named branch before switching; `"import pyodbc; print(pyodbc.drivers())"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 2.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 2 starting-screen checklist and re-verify the active context.

Lesson 2.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 2 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — config/

Exact folder name: config

Exact parent: repository root

Why it is needed now: Phase 2 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: config.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 2.D1.1 — Create the folder config

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\config" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\config" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\config"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\config" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\config" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\config" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — scripts/

Exact folder name: `scripts`

Exact parent: `repository root`

Why it is needed now: Phase 2 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `repository root` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `scripts`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 2.D2.1 — Create the folder scripts

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — scripts/setup/

Exact folder name: `setup`

Exact parent: `scripts`

Why it is needed now: Phase 2 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `scripts` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `setup`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

Action 2.D3.1 — Create the folder scripts/setup

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts\setup" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\scripts\setup" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts\setup" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\scripts\setup" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts\setup" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\scripts\setup" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — requirements.txt

Exact filename: `requirements.txt`

Filename extension: `.txt`. In this project it identifies project text or configuration and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `.` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source

SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project text or configuration for Phase 2.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in . one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: requirements.txt.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled requirements.txt and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 2.F1.1 — Create the file requirements.txt from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\requirements.txt" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\requirements.txt" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\requirements.txt"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\requirements.txt" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "requirements.txt"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `..`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `requirements.txt`.
3. In PowerShell at the repository root, run `Test-Path ".\requirements.txt"` and require `True`.
4. Run `git status --short -- "requirements.txt"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for requirements.txt

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: text

Exact file: requirements.txt

Purpose: project text or configuration.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 2.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Runtime dependencies. Use Python 3.13.x for the local learning environment.
pandas>=2.2,<3.0
Faker>=30,<40
PyYAML>=6,<7
python-dotenv>=1,<2
pyarrow>=18,<23
SQLAlchemy>=2,<3
pyodbc>=5.2,<6
psycpg[binary]>=3.2,<4
tenacity>=9,<10
rich>=13,<15
```

Line-by-line explanation

- **Line 1:** `# Runtime dependencies. Use Python 3.13.x for the local learning environment.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `pandas>=2.2,<3.0` — `pandas` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `2.2` is a numeric literal used by the command or expression; `,` `<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3.0` is a numeric literal used by the command or expression
- **Line 3:** `Faker>=30,<40` — `Faker` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `30` is a numeric literal used by the command or expression; `,` `<` is a

name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 40 is a numeric literal used by the command or expression

- **Line 4:** `PyYAML>=6,<7` — `PyYAML` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `6` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `7` is a numeric literal used by the command or expression
- **Line 5:** `python-dotenv>=1,<2` — `python-dotenv` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `1` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `2` is a numeric literal used by the command or expression
- **Line 6:** `pyarrow>=18,<23` — `pyarrow` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `18` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `23` is a numeric literal used by the command or expression
- **Line 7:** `SQLAlchemy>=2,<3` — `SQLAlchemy` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `2` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3` is a numeric literal used by the command or expression
- **Line 8:** `pyodbc>=5.2,<6` — `pyodbc` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `5.2` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `6` is a numeric literal used by the command or expression
- **Line 9:** `psycopg[binary]>=3.2,<4` — `psycopg` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `binary` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `]>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3.2` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `4` is a numeric literal used by the command or expression
- **Line 10:** `tenacity>=9,<10` — `tenacity` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `9` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `10` is a numeric literal used by the command or expression
- **Line 11:** `rich>=13,<15` — `rich` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `13` is a numeric literal used by the command or expression; `,<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `15` is a numeric literal used by the command or expression

[Back to the Phase 2 lesson index](#)

File introduction — requirements-dev.txt

Exact filename: requirements-dev.txt

Filename extension: .txt. In this project it identifies project text or configuration and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: . relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project text or configuration for Phase 2.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in . one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: requirements-dev.txt.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled requirements-dev.txt and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 2.F2.1 — Create the file requirements-dev.txt from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\requirements-dev.txt" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\requirements-dev.txt" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\requirements-dev.txt"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\requirements-dev.txt" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add -Force, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "requirements-dev.txt"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under ..
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `requirements-dev.txt`.
3. In PowerShell at the repository root, run `Test-Path ".\requirements-dev.txt"` and require True.
4. Run `git status --short -- "requirements-dev.txt"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for requirements-dev.txt

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: text

Exact file: `requirements-dev.txt`

Purpose: project text or configuration.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 2.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-r requirements.txt
pytest>=8,<10
pytest-cov>=5,<7
ruff>=0.9,<1.0
nbformat>=5,<6
nbconvert>=7,<8
jsonschema>=4,<5
```

Line-by-line explanation

- **Line 1:** `-r requirements.txt` — `-r` is a command option or flag; its exact behavior is defined beside the command; `requirements.txt` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `pytest>=8,<10` — `pytest` the Python test runner; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `8` is a numeric literal used by the command or expression; `<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `10` is a numeric literal used by the command or expression
- **Line 3:** `pytest-cov>=5,<7` — `pytest-cov` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `5` is a numeric literal used by the command or expression; `<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `7` is a numeric literal used by the command or expression

[Back to the Phase 2 lesson index](#)

File introduction — config/dev.example.yml

Exact filename: dev.example.yml

Filename extension: .yml. In this project it identifies human-readable configuration and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: config relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: human-readable configuration for Phase 2.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? Yes—review carefully before Git staging.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in config one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: dev.example.yml.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled dev.example.yml and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 2.F3.1 — Create the file config/dev.example.yml from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\config\dev.example.yml" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\config\dev.example.yml" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\config\dev.example.yml` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\config\dev.example.yml" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "config/dev.example.yml"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `config`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `config/dev.example.yml`.
3. In PowerShell at the repository root, run `Test-Path ".\config\dev.example.yml"` and require `True`.
4. Run `git status --short -- "config/dev.example.yml"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for config/dev.example.yml

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: YAML

Exact file: `config/dev.example.yml`

Purpose: human-readable configuration.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 2.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

environment: dev
paths:
  generated_data: datasets/generated/quick
  extracts: datasets/raw
  logs: logs

[Back to the Phase 2 lesson index](#)

File introduction — scripts/setup/verify_local_tools.ps1

Exact filename: verify_local_tools.ps1

Filename extension: .ps1. In this project it identifies Windows automation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: scripts/setup relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: Windows automation for Phase 2.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in scripts/setup one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: verify_local_tools.ps1.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled verify_local_tools.ps1 and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 2.F4.1 — Create the file scripts/setup/verify_local_tools.ps1 from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\setup\verify_local_tools.ps1" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\scripts\setup\verify_local_tools.ps1" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts\setup\verify_local_tools.ps1" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\scripts\setup\verify_local_tools.ps1" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/setup/verify_local_tools.ps1"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/setup`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/setup/verify_local_tools.ps1`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\setup\verify_local_tools.ps1"` and require True.
4. Run `git status --short -- "scripts/setup/verify_local_tools.ps1"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for scripts/setup/verify_local_tools.ps1

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: PowerShell

Exact file: `scripts/setup/verify_local_tools.ps1`

Purpose: Windows automation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 2.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Runs in: Windows PowerShell
# Purpose: show which required command-line tools Windows can find.
$ErrorActionPreference = "Continue"

$checks = @(
    @{ Name = "Git"; Command = "git --version" },
    @{ Name = "Python launcher"; Command = "py --version" },
    @{ Name = "Python"; Command = "python --version" },
    @{ Name = "VS Code"; Command = "code --version" },
    @{ Name = "PostgreSQL psql"; Command = "psql --version" }
```

```

)

foreach ($check in $checks) {
    Write-Host "`n=== $($check.Name) ==="
    try {
        Invoke-Expression $check.Command
    }
    catch {
        Write-Warning "$($check.Name) was not found on PATH. Read Phase 2 before changing PATH manually."
    }
}

Write-Host "`nSQL Server, SSMS, pgAdmin, Power BI Desktop, and Databricks are verified through their user interfaces."

```

Line-by-line explanation

- **Line 1:** # Runs in: Windows PowerShell is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** # Purpose: show which required command-line tools Windows can find. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 3:** \$ErrorActionPreference = "Continue" — \$ErrorActionPreference is a variable or environment-value reference rather than literal output; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "Continue" is a quoted literal; the quotation marks preserve spaces or mark text
- **Line 4:** blank line used only to separate logical sections for readability.
- **Line 5:** \$checks = @(— \$checks is a variable or environment-value reference rather than literal output; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

[Back to the Phase 2 lesson index](#)

What your screen should look like now

- Every Phase 2 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 2.3 completion checklist

☐

requirements.txt was created by me, saved, located correctly, and inspected — [STATUS]

☐

requirements-dev.txt was created by me, saved, located correctly, and inspected — [STATUS]

☐

config/dev.example.yml was created by me, saved, located correctly, and inspected — [STATUS]

☐

scripts/setup/verify_local_tools.ps1 was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 2.4](#) and recheck the root and branch.

Lesson 2.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 2.4.G1 — Inspect the current state without changing it

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.

2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.4.G2 — Create the smallest required object or decision

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Create the smallest required object or decision. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.

4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.4.G3 — Run the phase-specific verification

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run the phase-specific verification. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.4.G4 — Demonstrate one safe failure or alternate-result branch

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

Action 2.4.G5 — Record evidence and prepare the downstream handoff

Application:

Web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 2 lesson index](#)

What your screen should look like now

- The new Phase 2 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 2.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 2.5](#).

Lesson 2.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 2 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Tool editions and stable versions

Question:

Which product editions should support a no-production-use learning project?

Options considered:

- Latest stable free/developer editions.
- Preview/beta versions.
- Paid enterprise editions.

Beginner path selected:

Use current stable free or Developer editions and record exact versions.

Why this path was selected:

This maximizes learning value while avoiding production licensing claims and beta instability.

Tradeoff:

The interface can change monthly and free tiers have limits.

What a company might do instead:

A company standardizes supported versions, patch windows, licenses, and managed deployment.

How to explain this in an interview:

I verified the exact tool versions and chose stable, supported editions appropriate for non-production development.

Design decision — SQL Server edition

Question:

Which SQL Server edition is appropriate for this non-production portfolio project?

Options considered:

- Developer edition for full non-production features.
- Express edition for a smaller free footprint.
- A paid production edition.

Beginner path selected:

Prefer current SQL Server Developer for non-production learning; use Express only when machine constraints require its limits.

Why this path was selected:

Developer provides the broadest learning surface without a production-use claim, while Express is a practical fallback on constrained hardware.

Tradeoff:

Developer may use more resources, and neither choice authorizes production deployment.

What a company might do instead:

A company selects and licenses an edition from workload, availability, security, support, and cost requirements, often using managed Azure SQL services.

How to explain this in an interview:

I selected a current stable non-production edition, recorded the exact version, and documented licensing and resource limits rather than treating all SQL Server editions as interchangeable.

Design decision — PostgreSQL installation method

Question:

How should PostgreSQL be installed on a beginner Windows computer?

Options considered:

- Official Windows installer with the database service and pgAdmin.
- Docker container.
- Windows Subsystem for Linux package installation.

Beginner path selected:

Use the official Windows installer and verify the Windows service, port, superuser choice, and pgAdmin connection.

Why this path was selected:

It gives the most visible Windows-native service and GUI workflow and avoids requiring Docker or Linux knowledge before database fundamentals.

Tradeoff:

The installer adds a local service and requires careful password, port, PATH, and upgrade management.

What a company might do instead:

Teams often standardize containers, managed PostgreSQL, automated images, secrets, backups, and infrastructure as code.

How to explain this in an interview:

I used the official Windows installer for transparent beginner setup, while documenting containers and managed services as reproducibility and operations alternatives.

If you see Result A

The version command opens the expected stable tool and prints a version. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

The command is not recognized, resolves to a different executable, or the UI version differs. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Web browser, Windows Settings, installers, PowerShell, VS Code, SSMS, pgAdmin, Databricks, and Power BI Desktop.

Window/panel: Show version commands, VS Code interpreter, SSMS connection, pgAdmin tree, Databricks workspace, and Power BI About dialog.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase02_install-and-verify-the-windows-toolchain_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 2's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 2 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 2.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Interpret git status --short

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 2.5.G4 — Inspect the unstaged diff for requirements.txt

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "requirements.txt"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "requirements.txt"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"requirements.txt"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.5.G5 — Stage only the reviewed file `requirements.txt`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "requirements.txt"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "requirements.txt"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"requirements.txt"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 2.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

[Back to the Phase 2 lesson index](#)

Action 2.5.G7 — Create the Phase 2 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "docs: record verified local toolchain versions"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "docs: record verified local toolchain versions"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"docs: record verified local toolchain versions"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Action 2.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 2 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message docs: record verified local toolchain versions and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 2.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 2 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 2 created the verified boundary described by **Install and verify the Windows toolchain**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 2 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

What I can now explain without help:

[WRITE YOUR ANSWER]

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 2.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 3 uses the verified editor and Git workflow to create requirements safely.

Phase 2 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 3 — Write business requirements and acceptance criteria

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: A working repository and toolchain.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 4 turns approved requirements, grains, KPIs, and quality expectations into source schemas.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 3 lesson index

1. [Lesson 3.1 — Understand the phase and starting screen](#)
2. [Lesson 3.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 3.3 — Create and understand the phase files](#)
4. [Lesson 3.4 — Build and validate required objects](#)
5. [Lesson 3.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 3.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** VS Code, Markdown Preview, Windows PowerShell, and Git.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 3 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 2 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 3 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

VS Code, Markdown Preview, Windows PowerShell, and Git. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 3 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.

- No new Phase 3 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 3 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 3.1 completion checklist

☐

I read why Phase 3 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 3.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 3 lesson index](#)

Lesson 3.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 3 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A reviewed business requirements package containing company context, stakeholders, pain points, user stories, KPI contracts, freshness and quality targets, security assumptions, success criteria, out-of-scope items, risks, and assumptions.

2. Why it matters

Code can be technically correct and still answer the wrong business question. Requirements determine grain, date role, filters, currency, attribution, and quality thresholds. They also prevent scope creep by stating what the first project will not solve.

3. Words to know

Term	Plain-language definition
Stakeholder	Person or team making a decision with the data.
User story	Short statement of who needs what and why.
KPI	Governed measure tied to a decision.
Numerator / denominator	Top and bottom parts of a rate.

Term	Plain-language definition
Filter	Condition limiting which records count.
Date role	Which business date controls a metric, such as order or return date.
Freshness target	How recent data should be.
Success criterion	Observable condition proving the requirement is met.
Out of scope	Deliberate boundary for this version.
Assumption	Decision accepted without full evidence, recorded for review.
Risk	Uncertain event that could damage trust, schedule, cost, or security.
Acceptance criteria	Specific checks defining task completion.

4. What must already be completed

Phase 0 mental model and Phase 1 repository setup are complete. Tool installation is helpful but not required to edit Markdown.

5. Applications to open

Application	How to open it	Why it is open
VS Code	Open the verified repository root with code ..	Edit requirements and logs.
Web browser	Open only official references when a current platform constraint affects a requirement.	Validate tier/capability assumptions.
PowerShell	Open repository root.	Check files and Git diff.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
Get-Content .\docs\business_requirements.md -TotalCount 40	Prints the beginning of the requirement document.	Confirms you are editing the intended file and can inspect it outside VS Code.
Select-String -Path .\docs\kpi_definitions.md -Pattern '^### [0-9]+.'	Lists KPI section headings.	Confirms every required KPI definition exists.
git diff -- docs\business_requirements.md docs\assumption_log.md docs\risk_register.md	Shows only your requirement edits.	Requirements changes should be reviewed as carefully as code.

Why requirements come before code

Consider “return rate.” It could mean returned orders / orders, returned units / sold units, refund amount / revenue, purchase-date cohorts, or return-date activity. Those choices require different grains and date relationships. Writing SQL before choosing makes disagreement inevitable.

Vertical-slice decision summary

The first slice should prove one customer, product, order, order item, clean Silver rule, dimension lookup, sales fact, revenue calculation, and validation. Breadth comes after the smallest trustworthy path works.

MY TASK

Rewrite one KPI definition in your own words, document one assumption and one risk, and define the first vertical slice acceptance criteria without changing the required overall scope.

STARTER SKELETON

```
## TODO(USER) KPI decision
- Stakeholder and decision:
- Business meaning:
- Numerator:
- Denominator:
- Grain:
- Date role:
- Filters/exclusions:
- Currency:
- Source columns:
- SQL validation:
- Common misuse:

## TODO(USER) Vertical slice acceptance criteria
- Given _____
- When _____
- Then source count _____
- And Silver rejects _____
- And Gold grain _____
- And revenue equals _____
```

Acceptance criteria: One KPI contract is complete enough that another person can independently reproduce it; one assumption/risk is owned; first-slice criteria are measurable and do not claim execution.

HINT 1 — CONCEPT

A stakeholder needs a decision, not 'a dashboard'.

HINT 2 — PSEUDOCODE

Write the denominator first for rates; most interpretation errors hide there.

HINT 3 — NEAR-COMPLETE PATTERN

Use the KPI catalog fields as a near-complete checklist, then rewrite the wording yourself.

13. Expected files or output

- Edited assumption/risk logs.
- One personally rewritten KPI contract.
- A vertical-slice acceptance list.
- No SQL code added solely to avoid deciding definitions.

14. How to verify

- A reader can state one row's grain and the KPI's date role.
- Every required KPI maps to existing or planned columns.
- Freshness and success statements are targets until measured.
- Out-of-scope items include streaming/CDC/cloud production.

15. Automated tests

- Manual requirement trace: KPI → columns → source table → Silver rule → Gold fact → DAX/SQL.
- Link check later ensures requirement references resolve.

- No platform automation test is a substitute for stakeholder definition review.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
KPI has two possible denominators	Business definition is unresolved.	Write sample numbers and calculate each interpretation.	Choose one for Track A, name the other separately, record assumption.	A new reader gets one answer from the contract.
Freshness target is written as achieved	Target and evidence are being confused.	Search for words 'achieved', 'runs daily', or performance claims.	Change to target/desired until run history proves it.	README status remains honest.
Every idea became in scope	No prioritization boundary.	Compare against Phase 22 extensions.	Move non-required ideas to optional extensions with prerequisites/evidence.	Required checklist stays feasible.
KPI cannot map to columns	Source model lacks needed data or definition is too vague.	Use data dictionary filter by table/column.	Add a justified source column before DDL, or change/out-scope KPI.	Mapping is explicit.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why can return rate be correct mathematically but wrong for the business?
2. What is the difference between a freshness target and a verified service level?
3. How does declared grain constrain a KPI?
4. Why record an assumption instead of quietly treating it as fact?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What four details must be aligned for a ratio across two facts?
2. Why is ROAS attribution an assumption rather than a simple join?
3. What is one success criterion that proves trust rather than file existence?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture the edited KPI contract and assumption log side by side. The image should show your own wording and no fabricated values.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
docs: define northstar business requirements and KPI contracts
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Stakeholders/decisions reviewed — [STATUS]

☐

All required KPIs mapped — [STATUS]

☐

Freshness targets labeled honestly — [STATUS]

☐

Quality expectations mapped to tests — [STATUS]

☐

Security assumptions reviewed — [STATUS]

☐

Risk and assumption added — [STATUS]

☐

Vertical slice accepted — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-3. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-3] (the answer-key section immediately after the quiz in this workbook#phase-3).

Next phase: Phase 4 turns those requirements into normalized SQL Server and PostgreSQL source schemas.

Required action cards

Action 3.2.1 — Open docs/business_requirements.md and read the business problem aloud.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open docs/business_requirements.md and read the business problem aloud. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open docs/business_requirements.md and read the business problem aloud.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Open docs/business_requirements.md and read the business problem aloud.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.2.2 — For each stakeholder, identify one decision—not merely one chart—they need to make.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

For each stakeholder, identify one decision—not merely one chart—they need to make. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: For each stakeholder, identify one decision—not merely one chart—they need to make.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

For each stakeholder, identify one decision—not merely one chart—they need to make.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.2.10 — Write acceptance criteria for the first vertical slice: customers + products + one valid sales line from source

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Write acceptance criteria for the first vertical slice: customers + products + one valid sales line from source. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Write acceptance criteria for the first vertical slice: customers + products + one valid sales line from source through a SQL validation query.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 10

Action

Write acceptance criteria for the first vertical slice: customers + products + one valid sales line from source through a SQL validation query.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Content .\docs\business_requirements.md -TotalCount 40
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Content .\docs\business_requirements.md -TotalCount 40 — Get-Content is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; . is a path, relative location, branch-style name, or file argument; verify every character before running it; docs is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; business_requirements.md is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -TotalCount is a command option or flag; its exact behavior is defined beside the command; 40 is a numeric literal used by the command or expression

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Action 3.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Select-String -Path .\docs\kpi_definitions.md -Pattern '^## [0-9]+\.'
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `Select-String -Path .\docs\kpi_definitions.md -Pattern '^## [0-9]+\.'` — `Select-String` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `docs` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `kpi_definitions.md` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Pattern` is a command option or flag; its exact behavior is defined beside the command; `'^## [0-9]+\.'` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Action 3.2.C3 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
git diff -- docs\business_requirements.md docs\assumption_log.md docs\risk_register.md
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- docs\business_requirements.md docs\assumption_log.md docs\risk_register.md` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `docs` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `business_requirements.md` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `docs` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `assumption_log.md` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `docs` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `risk_register.md` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 3.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 3 starting-screen checklist and re-verify the active context.

Lesson 3.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 3 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — docs/

Exact folder name: docs

Exact parent: repository root

Why it is needed now: Phase 3 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: docs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 3.D1.1 — Create the folder docs

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\docs" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\docs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\docs" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — docs/business_requirements.md

Exact filename: `business_requirements.md`

Filename extension: `.md`. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `docs` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 3.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `docs` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `business_requirements.md`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `business_requirements.md` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 3.F1.1 — Create the file docs/business_requirements.md from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\business_requirements.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\docs\business_requirements.md" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\docs\business_requirements.md" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\docs\business_requirements.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/business_requirements.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `docs`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/business_requirements.md`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\business_requirements.md"` and require `True`.
4. Run `git status --short -- "docs/business_requirements.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for docs/business_requirements.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: docs/business_requirements.md

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 3.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Business Requirements

## Company background

Northstar Retail is a fictional omnichannel retailer with physical stores and an e-commerce website. Its operational sales, customer, product, employee, shipment, and inventory data live in SQL Server. Website behavior and marketing activity live in PostgreSQL. Returns, supplier cost changes, promotions, and tracking events arrive as files.

## Business problem

Leadership has inconsistent reports because sales, customers, inventory, website behavior, marketing, shipments, and returns live in separate systems. The company needs a governed data platform that produces trusted daily metrics and supports executive, sales, operations, marketing, and customer analysis.

## Stakeholders

| Stakeholder | Decision | Needed information | Primary concern |
|---|---|---|---|
| Chief Executive Officer | Overall business direction | Revenue, profit, customer, operations health | One trusted summary |
| Finance leader | Profitability and reconciliation | Revenue, COGS, gross profit, discounts, refunds | Definitions and tie-outs |
| Sales leader | Channel/store performance | Orders, AOV, revenue, margin | Comparable stores and channels |
| Merchandising | Product and category choices | Units, margin, discount, return rate | Product-level grain |
| Marketing | Campaign allocation | Spend, sessions, conversion, attributed revenue | Attribution assumptions |
| Operations | Inventory and shipping | On hand, risk, delivery performance | Timeliness and exceptions |
| Customer experience | Returns and delays | Return reasons, late shipments | Traceable order detail |
| Data engineering | Reliability | Freshness, quality, lineage, rerun safety | Recoverable batches |
| Analysts | Self-service reporting | Star schema and semantic measures | Clear definitions |

## User stories

- As an executive, I need a daily overview so I can identify material changes without reconciling multiple reports.
- As a finance analyst, I need line-level revenue and cost logic so I can reproduce gross profit.
- As a store leader, I need store and region comparisons so I can investigate underperformance.
- As a marketer, I need spend, sessions, and converting orders joined under a documented attribution rule.
- As an inventory planner, I need latest store-product stock and reorder thresholds so I can prioritize replenishment.
- As a data engineer, I need batch manifests, tests, quarantine records, and idempotent tasks so failed loads can be repaired safely.

## Business questions

1. How much revenue and gross profit are we generating?
2. Which products, categories, stores, regions, and channels perform best?
3. What is average order value?
4. What is the return rate?
5. What percentage of delivered shipments arrive on time?
6. Which promotions create profitable sales?
7. How does website activity convert into orders?
8. How effective is marketing spend by channel and campaign?
9. Which products are at risk of stocking out?
10. How many new versus returning customers do we have?

Definitions and validation methods are in [`${kpi_definitions.md}`](kpi_definitions.md).

## Freshness targets

| Data domain | Target for this portfolio | Reason |
|---|---|---|
| Sales/orders/payments | Daily by 8:00 AM local reporting time | Executive and store reporting |
| Shipments/returns | Daily by 9:00 AM | Operations and customer experience |
| Inventory snapshot | Daily after source snapshot closes | Avoid summing partial snapshots |
| Website events/sessions | Daily | Batch learning scope |
| Marketing spend | Daily when feed is available | Campaign pacing |
| Power BI | Refresh only after warehouse publication succeeds | Prevent partial reports |

These are learning objectives, not measured service-level agreements until you schedule and observe several verified runs.

## Data-quality expectations

- Required keys are not null in trusted tables.
- Fact grain is unique.
- Dimension references resolve or intentionally use unknown key `0`.
- Sales arithmetic reconciles within one cent per row.
- Source manifests tie to Bronze accepted plus unreadable records.
- Bronze ties to Silver valid plus quarantined records.
- Silver ties to Gold under documented filtering/deduplication rules.
- Currency is USD in the beginner path; non-USD rows are quarantined until conversion is designed.
```

- Dates are parseable, event order is plausible, and timestamps are normalized to UTC.
- No required quality check is hidden or filtered out before publication.

Security assumptions

- All data is synthetic, but customer-like fields are treated as synthetic PII for practice.
- Local credentials belong only in `.env`, which is ignored by Git.
- Databricks credentials belong in secret management or supported identity mechanisms, never notebooks.
- Analysts receive read-only access to serving schemas/views.
- Screenshots must not expose passwords, tokens, connection strings, personal workspace email, or local paths unnecessarily.

Success criteria

The project is successful only when Kirolos has personally verified the gates in the final definition-of-done section in this workbook, can reproduce KPI values in SQL and Power BI, can explain every major design choice, and has screenshot/run evidence. Files existing in Git are not proof of execution.

Out of scope for the required path

- Real customer data, production operations, or legal compliance certification.
- Streaming, CDC, Kafka, production IaC, or automated cloud networking.
- Multi-currency conversion and financial accounting close.
- Causal campaign attribution.
- A fabricated `.pbix` file or fabricated Databricks run.
- Production-scale performance claims.

Assumption log template

ID	Assumption	Why	How to test or revisit	Status
A-001	USD is the reporting currency in Track A	Keeps beginner calculations interpretable	Add FX source and effective-rate rules in an extension	Accepted for Track A
A-002	One sales fact row equals one valid order item	Supports additive revenue and product analysis	Run grain uniqueness and source reconciliation	Must verify
A-003	A shipment is on time when actual date <= promised date	Common operational definition	Confirm business owner treatment of missing dates	Must verify
A-004	Converting session order ID provides simplified attribution	Source has a direct link for some sessions	Check duplicate order links; document last-session limitation	Must verify
A-005	Manual upload/download is acceptable for learning	Avoids unsupported localhost connectivity claims	Move to Track B only with network-accessible sources	Accepted for Track A

File introduction — docs/risk_register.md

Exact filename: risk_register.md

Filename extension: .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: docs relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 3.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: risk_register.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled risk_register.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 3.F2.1 — Create the file docs/risk_register.md from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\risk_register.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\risk_register.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\docs\risk_register.md` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\docs\risk_register.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/risk_register.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under docs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/risk_register.md`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\risk_register.md"` and require `True`.
4. Run `git status --short -- "docs/risk_register.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for docs/risk_register.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: `docs/risk_register.md`

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 3.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

Risk Register

```
| ID | Risk | Probability | Impact | Early warning | Mitigation | Owner | Status |
|---|---|---|---|---|---|---|---|
| R-001 | Credentials are committed | Medium | High | `.env` appears in `git status` | `.gitignore`, secret scan, rotate immediately if exposed | Kirolos | Open |
| R-002 | Databricks cannot see local source | High if misunderstood | Medium | JDBC timeout to localhost | Use Track A volume handoff; do not tunnel casually | Kirolos | Mitigated by design |
| R-003 | Duplicate rerun inflates facts | Medium | High | Same batch doubles row count | Batch deletion/merge, unique grain tests, max concurrent runs 1 | Data engineering | Open until verified |
| R-004 | SCD2 facts join to current instead of event-time row | Medium | High | Historical reports change after customer/product update | Effective-date join tests and worked example | Data engineering | Open |
| R-005 | Return rate mixes incompatible date roles | Medium | Medium | SQL and dashboard disagree by period | Label purchase-date vs return-date view; validation samples | Analytics | Open |
| R-006 | Free-tier quotas interrupt learning runs | Medium | Low | Compute unavailable or quota warning | Use quick/small scale, stop retries, preserve outputs | Kirolos | Monitor |
| R-007 | Power BI ambiguous relationships change totals | Medium | High | Warning icon or totals vary unexpectedly | Single-direction star schema, inactive role dates, SQL validation | Kirolos | Open |
| R-008 | Larger generated files enter Git | Medium | Medium | Git status shows datasets/raw or generated | `.gitignore`, publish quick sample only | Kirolos | Mitigated by config |
| R-009 | Reference TODO is mistaken for completed work | Medium | High | README claims verified results without evidence | Status labels, checklist, screenshot proof, replace placeholders only after verification | Kirolos | Open |
| R-010 | Schema changes break ingestion | Medium | Medium | read/merge error or missing column | Schema drift tests, quarantine, explicit column lists | Data engineering | Open |
```

Line-by-line explanation

- Line 1:** # Risk Register is a comment for a human reader; it normally does not change data or execute business logic.
- Line 2:** blank line used only to separate logical sections for readability.
- Line 3:** | ID | Risk | Probability | Impact | Early warning | Mitigation | Owner | Status | — ID is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Risk is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Probability is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Impact is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Early is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; warning is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Mitigation is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Owner is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Status is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 4:** |---|---|---|---|---|---|---| — --- is a command option or flag; its exact behavior is defined beside the command; --- is a command option or flag; its exact behavior is defined beside the command; ---: is a command option or flag; its exact behavior is defined beside the command; ---: is a command option or flag; its exact behavior is defined beside the command; --- is a command option or flag; its exact behavior is defined beside the command; --- is a command option or flag; its exact behavior is defined beside the command; --- is a command option or flag; its exact behavior is defined beside the command
- Line 5:** | R-001 | Credentials are committed | Medium | High | `.env` appears in `git status` | `.gitignore`, secret scan, rotate immediately if exposed | Kirolos | Open | — R-001 is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Credentials is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; are is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; committed is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Medium is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; High is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; is a path, relative location, branch-style name, or file argument; verify every character before running it; env is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; appears is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; in is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; git calls the Git version-control program; status shows tracked, staged, modified, and untracked work; remaining punctuation and identifiers continue the same statement.
- Line 6:** | R-002 | Databricks cannot see local source | High if misunderstood | Medium | JDBC timeout to localhost | Use Track A volume handoff; do not tunnel casually | Kirolos | Mitigated by design | — R-002 is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;

[Back to the Phase 3 lesson index](#)

File introduction — docs/assumption_log.md

Exact filename: assumption_log.md

Filename extension: .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: docs relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 3.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: assumption_log.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled assumption_log.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 3.F3.1 — Create the file docs/assumption_log.md from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\assumption_log.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\docs\assumption_log.md" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\docs\assumption_log.md" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\docs\assumption_log.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/assumption_log.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under docs.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with docs/assumption_log.md.
3. In PowerShell at the repository root, run `Test-Path ".\docs\assumption_log.md"` and require True.
4. Run `git status --short -- "docs/assumption_log.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for docs/assumption_log.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: docs/assumption_log.md

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 3.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Assumption Log

Update this file whenever you make a decision without complete evidence.

| ID | Date | Assumption or decision | Owner | Evidence | Risk if wrong | Review date | Status |
|----|----|-----|-----|-----|-----|-----|-----|
| A-001 | [DATE] | Track A reports in USD only. | Kirolos | Project scope | Non-USD rows are excluded rather than converted. | [DATE] | Accepted for Track A |
| A-002 | [DATE] | [ADD YOUR ASSUMPTION] | [OWNER] | [LINK/QUERY] | [RISK] | [DATE] | Open |
```

Line-by-line explanation

- **Line 1:** # Assumption Log is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** blank line used only to separate logical sections for readability.
- **Line 3:** Update this file whenever you make a decision without complete evidence. — Update is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; this is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; file is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; whenever is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; you is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; make is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; a is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; decision is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; without is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; complete is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; evidence is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; . is a path, relative location, branch-style name, or file argument; verify every character before running it
- **Line 4:** blank line used only to separate logical sections for readability.

[Back to the Phase 3 lesson index](#)

What your screen should look like now

- Every Phase 3 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 3.3 completion checklist

☐

docs/business_requirements.md was created by me, saved, located correctly, and inspected — [STATUS]

☐

docs/risk_register.md was created by me, saved, located correctly, and inspected — [STATUS]

☐

docs/assumption_log.md was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with `Ctrl+S`. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 3.4](#) and recheck the root and branch.

Lesson 3.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 3.4.G1 — Inspect the current state without changing it

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.4.G2 — Create the smallest required object or decision

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Create the smallest required object or decision. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.4.G3 — Run the phase-specific verification

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run the phase-specific verification. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.4.G4 — Demonstrate one safe failure or alternate-result branch

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 3 lesson index](#)

Action 3.4.G5 — Record evidence and prepare the downstream handoff

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

What your screen should look like now

- The new Phase 3 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 3.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 3.5](#).

Lesson 3.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 3 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Verification before automation

Question:

Should the phase prioritize a visible manual verification or jump directly to automation?

Options considered:

- Manual verification first, then automation.
- Automation without a known-good baseline.
- Manual operation forever.

Beginner path selected:

Establish one verified manual baseline and then automate repeatable checks.

Why this path was selected:

A known-good example makes failures interpretable and prevents automation from hiding a wrong assumption.

Tradeoff:

The first run takes longer.

What a company might do instead:

Teams often pair infrastructure as code and automated tests with controlled bootstrap and acceptance procedures.

How to explain this in an interview:

I established a verified baseline, then encoded the same contract in tests and orchestration so automation preserved meaning rather than just speed.

If you see Result A

Every requirement maps to an owner, metric, source, acceptance criterion, and limitation. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

A requirement is vague, unmeasurable, unsupported by a source, or missing an acceptance test. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: VS Code, Markdown Preview, Windows PowerShell, and Git.

Window/panel: Show requirements section plus acceptance-criteria mapping.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase03_write-business-requirements-and-acceptance-criteria_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 3's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 3 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 3.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Action 3.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Action 3.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Interpret git status --short

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 3.5.G4 — Inspect the unstaged diff for docs/business_requirements.md

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "docs/business_requirements.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "docs/business_requirements.md"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"docs/business_requirements.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Action 3.5.G5 — Stage only the reviewed file `docs/business_requirements.md`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "docs/business_requirements.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "docs/business_requirements.md"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"docs/business_requirements.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

[Back to the Phase 3 lesson index](#)

Action 3.5.G7 — Create the Phase 3 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "docs: define northstar business requirements"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "docs: define northstar business requirements"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"docs: define northstar business requirements"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Action 3.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 3.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 3 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `docs: define northstar business requirements` and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 3.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.

9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 3 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 3 created the verified boundary described by **Write business requirements and acceptance criteria**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 3 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

What I can now explain without help:

[WRITE YOUR ANSWER]

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 3.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 4 turns approved requirements, grains, KPIs, and quality expectations into source schemas.

Phase 3 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 4 — Design and create the SQL Server and PostgreSQL source systems

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Written business requirements and source placement decisions.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 5 uses each column, constraint, and relationship as a generation requirement.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 4 lesson index

1. [Lesson 4.1 — Understand the phase and starting screen](#)
2. [Lesson 4.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 4.3 — Create and understand the phase files](#)
4. [Lesson 4.4 — Build and validate required objects](#)
5. [Lesson 4.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 4.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** VS Code, SSMS, pgAdmin, and PowerShell.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 4 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 3 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 4 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

VS Code, SSMS, pgAdmin, and PowerShell. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 4 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 4 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 4 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 4.1 completion checklist

☐

I read why Phase 4 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 4.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 4 lesson index](#)

Lesson 4.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 4 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

Two separate normalized operational databases: NorthstarRetail_ERP in Microsoft SQL Server, managed through SSMS, and northstar_digital in PostgreSQL, managed through pgAdmin or psql. Each has keys, constraints, indexes, audit columns, ERDs, safe idempotent setup, validation, and guarded development reset scripts.

2. Why it matters

Source systems optimize operational correctness and updates, not reporting convenience. Building them separately teaches dialect boundaries, client tools, service/connection concepts, normalization, and why the later warehouse model intentionally looks different.

3. Words to know

Term	Plain-language definition
T-SQL	SQL Server's SQL dialect.
PostgreSQL SQL	PostgreSQL's SQL dialect; similar but not interchangeable with T-SQL.
Normalized model	Entities separated to reduce update inconsistency and repetition.
Constraint	Database rule such as primary key, foreign key, unique, or check.
Index	Structure that speeds selected reads at storage/write cost.
Schema	Namespace inside a database, such as erp or digital.
DDL	Data Definition Language used to create/alter objects.
Idempotent DDL	Setup that can be rerun without blindly duplicating/replacing objects.
Object Explorer	SSMS tree for servers/databases/tables.
Query Tool	pgAdmin editor for PostgreSQL SQL.
Connection	Host/instance, port, database, authentication, and encryption settings.
Self-referencing key	Foreign key from a table to itself, such as employee manager.

4. What must already be completed

Phases 1–3 are complete. SQL Server engine, SSMS, PostgreSQL, pgAdmin, psql, and ODBC are installed/verified. You know the exact SQL Server service/instance and PostgreSQL port/password location.

5. Applications to open

Application	How to open it	Why it is open
SQL Server Configuration Manager or Windows Services	Search Start for the installed tool/service console.	Confirm SQL Server instance service name/running state.
SSMS	Start menu > SQL Server Management Studio.	Connect, run T-SQL, inspect ERP objects.
pgAdmin	Start menu > pgAdmin 4.	Connect/register server, create database, run PostgreSQL SQL.

Application	How to open it	Why it is open
Windows PowerShell	Repository root.	Diagnose services/ports and open files.
VS Code	Repository root.	Read DDL and ERDs before execution.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
Get-Service Where-Object { \$.Name -like 'MSSQL*' -or \$.DisplayName -like 'SQL Server (*)' } Format-Table Name, DisplayName, Status	Lists installed SQL Server engine services and state.	Server names must come from the actual instance, not a guess.
SELECT @@SERVERNAME AS server_name, SUSER_SNAME() AS login_name, DB_NAME() AS database_name;	Shows server, login, and current database.	DDL should never run against an assumed context.
-- Execute the entire opened 01_create_erp_database.sql file with the Execute button or F5.	Creates database and schemas only when missing.	Tables need a database/schema home.
-- Execute the entire opened 02_create_erp_tables.sql file.	Creates normalized ERP tables, constraints, and selected indexes.	The generator/loaders need real target structures.
Get-Service postgres Format-Table Name, Status, DisplayName	Lists PostgreSQL service state.	Connection refused often means the engine is stopped.
Test-NetConnection localhost -Port 5432	Tests whether a process accepts TCP connections on the PostgreSQL port.	Separates service/network issues from password/database issues.
-- Execute the entire opened 01_create_digital_schema.sql file using the Execute/Play button.	Creates digital/audit schemas, tables, constraints, and indexes.	Digital generated files need their own PostgreSQL source model.
psql -h localhost -p 5432 -U postgres -d northstar_digital	Starts an interactive PostgreSQL session; it prompts for password if required.	Provides an alternate tool and isolates pgAdmin-specific issues.

SQL dialect boundary

Concept	SQL Server / T-SQL	PostgreSQL SQL
Batch separator	GO client directive	none; use semicolons
Identity	IDENTITY(1,1)	generated identity/serial patterns
Current UTC	SYSUTCDATETIME()	now() returns timestampz
Top rows	SELECT TOP (10)	LIMIT 10
Conditional table	IF OBJECT_ID...	CREATE TABLE IF NOT EXISTS
Quoted identifier	[name] or ANSI quotes	"name"

Never paste `GO`, `TOP`, or `OBJECT_ID` into PostgreSQL. Never paste PostgreSQL `jsonb`, `timestampz`, or `DO $$` into T-SQL without translation.

MY TASK

Create both source databases, inspect every required table, explain two normalization choices, and add one justified non-unique index as a TODO(USER) exercise without constraining the deliberately dirty business key.

STARTER SKELETON

```
-- Dialect: SQL Server / T-SQL
-- TODO(USER): choose a real query pattern before adding an index.
USE NorthstarRetail_ERP;
GO
IF NOT EXISTS (
    SELECT 1 FROM sys.indexes
    WHERE object_id = OBJECT_ID(N'erp._____' )
    AND name = N'IX_____'
)
BEGIN
    CREATE INDEX IX_____
    ON erp._____(_____)
    INCLUDE (____);
END;
GO

-- TODO(USER) Explain the read benefit and write/storage cost.
```

Acceptance criteria: Both database contexts show all required tables; setup reruns without destructive errors; the added index is tied to a stated query pattern and does not block controlled quality issues.

HINT 1 — CONCEPT

Normalize around business entities and transactional update rules, not dashboard pages.

HINT 2 — PSEUDOCODE

Index columns used to filter/join/order frequently; INCLUDE columns can cover output without becoming key columns.

HINT 3 — NEAR-COMPLETE PATTERN

Model the existing IX_orders_updated_at pattern only after choosing a different table/query.

13. Expected files or output

- NorthstarRetail_ERP with schemas erp and audit.
- northstar_digital with schemas digital and audit.
- 13 ERP and 6 digital source tables.
- Object inventory query outputs.
- Journal records exact server/port/database context without passwords.

14. How to verify

- Run both source validation SQL files.
- Re-run creation scripts; no data/object replacement occurs.
- Inspect primary/foreign keys in SSMS and pgAdmin properties.
- Explain why customer_number is intentionally not unique in the source fixture.

15. Automated tests

- DDL object inventory.
- Database constraints prevent normal orphan records after load.
- Dialect header validation script checks every SQL file.
- Later loaders/reconciliation prove schema compatibility.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
SSMS cannot connect	Wrong instance/service/auth or certificate choice.	Service listing; SSMS exact error; try recorded instance only.	Start service and use actual server name/auth; do not enable broad insecure protocols blindly.	Context query succeeds.
Database already exists	Setup rerun or prior attempt.	SELECT DB_ID('Northstar-Retail_ERP');.	Use idempotent script; do not drop to silence.	Tables/inventory correct.
PostgreSQL connection refused	Service/port issue.	Service list and Test-NetConnection.	Start correct service/use recorded port.	pgAdmin/psql connects.
CREATE DATABASE cannot run in transaction	pgAdmin executed it in a transaction or database already exists.	Refresh Databases; inspect exact error.	Use pgAdmin Create Database UI; then connect to it before schema script.	Current database query returns northstar_digital.
Syntax error near GO/TOP/jsonb	Wrong dialect/tool.	Read first-line dialect header and current editor connection.	Run T-SQL in SSMS and PostgreSQL SQL in pgAdmin/psql.	Correct file executes.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why are SQL Server and PostgreSQL separate systems even though both use SQL?
2. Why does the operational source use normalized tables?
3. What tradeoff does an index introduce?
4. Why do guarded reset scripts still require judgment?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which application runs T-SQL in this project?
2. What does a foreign key protect?
3. Why was a unique constraint intentionally omitted from customer_number?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture SSMS Object Explorer expanded to NorthstarRetail_ERP > Tables and pgAdmin expanded to northstar_digital > Schemas > digital > Tables, plus context query outputs.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: create normalized sql server and postgres source schemas
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

SQL Server instance/context verified — [STATUS]

☐

ERP database/tables created — [STATUS]

☐

PostgreSQL server/port/context verified — [STATUS]

☐

Digital database/tables created — [STATUS]

☐

DDL rerun safety verified — [STATUS]

☐

ERDs and normalization explained — [STATUS]

☐

Source validation queries run — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-4. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-4] (the answer-key section immediately after the quiz in this workbook#phase-4).

Next phase: Phase 5 generates reproducible fictional data, including controlled defects for Silver.

Required action cards

Action 4.2.1 — Open docs/images/sqlserver_erd.svg and postgres_erd.svg. For each table, state its primary key and one par

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Open docs/images/sqlserver_erd.svg and postgres_erd.svg. For each table, state its primary key and one par. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open docs/images/sqlserver_erd.svg and postgres_erd.svg. For each table, state its primary key and one parent/child relationship.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Open docs/images/sqlserver_erd.svg and postgres_erd.svg. For each table, state its primary key and one parent/child relationship.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

Action 4.2.2 — In PowerShell, list SQL Server services. A default instance service is commonly MSSQLSERVER; a named Express

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

In PowerShell, list SQL Server services. A default instance service is commonly MSSQLSERVER; a named Express. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: In PowerShell, list SQL Server services. A default instance service is commonly MSSQLSERVER; a named Express instance commonly contains SQLEXPRESS, but use the actual result.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

In PowerShell, list SQL Server services. A default instance service is commonly MSSQLSERVER; a named Express instance commonly contains SQLEXPRESS, but use the actual result.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

Action 4.2.3 — Open SSMS. In , choose . Server name should match your verified instance, often localhost for default or `lo

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Open SSMS. In , choose . Server name should match your verified instance, often localhost for default or `lo. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open SSMS. In **Connect to Server**, choose **Database Engine**. Server name should match your verified instance, often localhost for default or localhost\SQLEXPRESS for Express. Choose Windows Authentication unless you intentionally configured SQL authentication. Check encryption/certificate options according to local official guidance.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

Open SSMS. In **Connect to Server**, choose **Database Engine**. Server name should match your verified instance, often localhost for default or localhost\SQLEXPRESS for Express. Choose Windows Authentication unless you intentionally configured SQL authentication. Check encryption/certificate options according to local official guidance.

Before continuing

Action 4.2.8 — Open pgAdmin. If the installer-created local server is not present, right-click . Give it a descriptive name;

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Open pgAdmin. If the installer-created local server is not present, right-click . Give it a descriptive name; . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open pgAdmin. If the installer-created local server is not present, right-click **Servers > Register > Server**. Give it a descriptive name; Connection host localhost, verified port, maintenance database postgres, username postgres or your configured admin. Save password only if your local security choice allows it.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 8****Action**

Open pgAdmin. If the installer-created local server is not present, right-click **Servers > Register > Server**. Give it a descriptive name; Connection host localhost, verified port, maintenance database postgres, username postgres or your configured admin. Save password only if your local security choice allows it.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

Action 4.2.9 — Expand the connected server, right-click , name it northstar_digital, owner your local admin, Save. This avo

Application:

Windows File Explorer

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Expand the connected server, right-click , name it northstar_digital, owner your local admin, Save. This avo. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Expand the connected server, right-click **Databases > Create > Database**, name it northstar_digital, owner your local admin, Save. This avoids rerun issues with CREATE DATABASE in a transaction.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows File Explorer. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 9

Action

Expand the connected server, right-click **Databases > Create > Database**, name it northstar_digital, owner your local admin, Save. This avoids rerun issues with CREATE DATABASE in a transaction.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

Action 4.2.C1 — Windows PowerShell

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Service | Where-Object { $_.Name -like 'MSSQL*' -or $_.DisplayName -like 'SQL Server (*)' } | Format-Table Name, DisplayName, Status
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `Get-Service | Where-Object { $_.Name -like 'MSSQL*' -or $_.DisplayName -like 'SQL Server (*)' } | Format-Table Name, DisplayName, Status` — `Get-Service` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Where-Object` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `{` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `$_` is a variable or environment-value reference rather than literal output; `-like` is a command option or flag; its exact behavior is defined beside the command; `'MSSQL*'` is a quoted literal; the quotation marks preserve spaces or mark text; `-or` is a command option or flag; its exact behavior is defined beside the command; `$_` is a variable or environment-value reference rather than literal output; `-like` is a command option or flag; its exact behavior is defined beside the command; `'SQL Server (*)'` is a quoted literal; the quotation marks preserve spaces or mark text; `}` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Format-Table` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Action 4.2.C2 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT @@SERVERNAME AS server_name, SUSER_SNAME() AS login_name, DB_NAME() AS database_name;
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT @@SERVERNAME AS server_name, SUSER_SNAME() AS login_name, DB_NAME() AS database_name; — SELECT requests data without changing it unless combined with a modifying statement; SERVERNAME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; server_name is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SUSER_SNAME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; login_name is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; DB_NAME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

Action 4.2.C3 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.

2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
-- Execute the entire opened 01_create_erp_database.sql file with the Execute button or F5.
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** -- Execute the entire opened 01_create_erp_database.sql file with the Execute button or F5. is a comment for a human reader; it normally does not change data or execute business logic.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 4.2.C4 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
-- Execute the entire opened 02_create_erp_tables.sql file.
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** -- Execute the entire opened 02_create_erp_tables.sql file. is a comment for a human reader; it normally does not change data or execute business logic.

Action 4.2.C5 — Windows PowerShell

Application:

pgAdmin 4 or PostgreSQL `psql`, as named in the action

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.

2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Service *postgres* | Format-Table Name, Status, DisplayName
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Service *postgres* | Format-Table Name, Status, DisplayName — Get-Service is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; * is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; postgres is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; * is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Format-Table is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Name is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Status is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; DisplayName is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

[Back to the Phase 4 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 4.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 4 starting-screen checklist and re-verify the active context.

Lesson 4.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 4 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — docs/

Exact folder name: docs

Exact parent: repository root

Why it is needed now: Phase 4 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: docs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 4.D1.1 — Create the folder docs

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\docs" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\docs" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\docs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\docs" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/

Exact folder name: `sql`

Exact parent: `repository root`

Why it is needed now: Phase 4 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `repository root` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `sql`.
7. PRESS: Enter.

8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 4.D2.1 — Create the folder sql

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: source.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 4.D6.1 — Create the folder sql/sqlserver/source

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql\sqlserver\source" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\sql\sqlserver\source" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\sql\sqlserver\source" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql\sqlserver\source" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\sqlserver\source" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\sqlserver\source" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — sql/sqlserver/source/01_create_erp_database.sql

Exact filename: 01_create_erp_database.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/sqlserver/source relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 4.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/sqlserver/source one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 01_create_erp_database.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 01_create_erp_database.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 4.F1.1 — Create the file sql/sqlserver/source/01_create_erp_database.sql from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\source\01_create_erp_database.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\source\01_create_erp_database.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\source\01_create_erp_database.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\sqlserver\source\01_create_erp_database.sql" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/source/01_create_erp_database.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/source`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/source/01_create_erp_database.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\source\01_create_erp_database.sql"` and require True.
4. Run `git status --short -- "sql/sqlserver/source/01_create_erp_database.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/source/01_create_erp_database.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/source/01_create_erp_database.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 4.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: SQL Server / T-SQL
-- Purpose: Create the local operational ERP database and schema safely.
-- Run in: SSMS query window connected to your local SQL Server instance.
-- Safety: This file creates missing objects. It does not drop existing data.

USE master;
GO

IF DB_ID(N'NorthstarRetail_ERP') IS NULL
BEGIN
    PRINT 'Creating database NorthstarRetail_ERP.';
    CREATE DATABASE NorthstarRetail_ERP;
END
ELSE
BEGIN
    PRINT 'Database NorthstarRetail_ERP already exists; leaving it in place.';
END;
GO
```

```

USE NorthstarRetail_ERP;
GO

IF SCHEMA_ID(N'erp') IS NULL
    EXEC(N'CREATE SCHEMA erp AUTHORIZATION dbo;');
GO

IF SCHEMA_ID(N'audit') IS NULL
    EXEC(N'CREATE SCHEMA audit AUTHORIZATION dbo;');
GO

IF OBJECT_ID(N'audit.source_load_batch', N'U') IS NULL
BEGIN
    CREATE TABLE audit.source_load_batch
    (
        batch_id          VARCHAR(80) NOT NULL PRIMARY KEY,
        process_name       VARCHAR(100) NOT NULL,
        started_at_utc     DATETIME2(3) NOT NULL CONSTRAINT DF_source_load_started DEFAULT SYSUTCDATETIME(),
        finished_at_utc    DATETIME2(3) NULL,
        status             VARCHAR(20) NOT NULL,
        source_file_count  INT          NULL,
        loaded_row_count   BIGINT       NULL,

[Back to the Phase 4 lesson index](#)

File introduction — `sql/sqlserver/source/02_create_erp_tables.sql`

Exact filename: `02_create_erp_tables.sql`

Filename extension: `.sql`. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `sql/sqlserver/source` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 4.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/sqlserver/source one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 02_create_erp_tables.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 02_create_erp_tables.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 4.F2.1 — Create the file sql/sqlserver/source/02_create_erp_tables.sql from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\source\02_create_erp_tables.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\source\02_create_erp_tables.sql" -ErrorAction Stop`
— `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\source\02_create_erp_tables.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\sqlserver\source\02_create_erp_tables.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add -Force, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/source/02_create_erp_tables.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/source`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/source/02_create_erp_tables.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\source\02_create_erp_tables.sql"` and require True.
4. Run `git status --short -- "sql/sqlserver/source/02_create_erp_tables.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/source/02_create_erp_tables.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/source/02_create_erp_tables.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 4.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: SQL Server / T-SQL
-- Purpose: Create the normalized ERP source tables.
-- Run in: SSMS query window connected to NorthstarRetail_ERP.
-- Idempotency: each table and index is created only when missing.

USE NorthstarRetail_ERP;
GO

[Back to the Phase 4 lesson index](#)

File introduction — sql/postgres/source/00_create_database.sql

Exact filename: 00_create_database.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/postgres/source relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 4.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/postgres/source one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 00_create_database.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 00_create_database.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 4.F3.1 — Create the file sql/postgres/source/00_create_database.sql from PowerShell

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\postgres\source\00_create_database.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\postgres\source\00_create_database.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\postgres\source\00_create_database.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\postgres\source\00_create_database.sql" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/postgres/source/00_create_database.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/postgres/source`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/postgres/source/00_create_database.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\postgres\source\00_create_database.sql"` and require True.
4. Run `git status --short -- "sql/postgres/source/00_create_database.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/postgres/source/00_create_database.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/postgres/source/00_create_database.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 4.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: PostgreSQL SQL
-- Run in: pgAdmin Query Tool while connected to the default 'postgres' database.
-- PostgreSQL cannot run CREATE DATABASE inside a transaction block.
-- Execute this statement once. If the database already exists, do not run it again.
CREATE DATABASE northstar_digital;
```

Line-by-line explanation

- **Line 1:** `-- Dialect: PostgreSQL SQL` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `-- Run in: pgAdmin Query Tool while connected to the default 'postgres' database.` is a comment for a human reader; it normally does not change data or execute business logic.

- **Line 3:** -- PostgreSQL cannot run CREATE DATABASE inside a transaction block. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 4:** -- Execute this statement once. If the database already exists, do not run it again. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 5:** CREATE DATABASE northstar_digital; — CREATE defines a new database object; DATABASE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; northstar_digital is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

File introduction — sql/postgres/source/01_create_digital_schema.sql

Exact filename: 01_create_digital_schema.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/postgres/source relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 4.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/postgres/source one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 01_create_digital_schema.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 01_create_digital_schema.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 4.F4.1 — Create the file sql/postgres/source/01_create_digital_schema.sql from PowerShell

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\postgres\source\01_create_digital_schema.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\postgres\source\01_create_digital_schema.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\postgres\source\01_create_digital_schema.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

File introduction — docs/data_dictionary.csv

Exact filename: data_dictionary.csv

Filename extension: .csv. In this project it identifies structured rows used as a definition, mapping, or fixture and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: docs relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: structured rows used as a definition, mapping, or fixture for Phase 4.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: data_dictionary.csv.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled data_dictionary.csv and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 4.F5.1 — Create the file docs/data_dictionary.csv from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\data_dictionary.csv" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\data_dictionary.csv" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\docs\data_dictionary.csv` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\docs\data_dictionary.csv" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/data_dictionary.csv"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `docs`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/data_dictionary.csv`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\data_dictionary.csv"` and require `True`.
4. Run `git status --short -- "docs/data_dictionary.csv"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

[Back to the Phase 4 lesson index](#)

File introduction — docs/source_to_target_mapping.csv

Exact filename: `source_to_target_mapping.csv`

Filename extension: `.csv`. In this project it identifies structured rows used as a definition, mapping, or fixture and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `docs` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: structured rows used as a definition, mapping, or fixture for Phase 4.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `source_to_target_mapping.csv`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `source_to_target_mapping.csv` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 4.F6.1 — Create the file docs/source_to_target_mapping.csv from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\source_to_target_mapping.csv" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\source_to_target_mapping.csv" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs\source_to_target_mapping.csv"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\docs\source_to_target_mapping.csv" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/source_to_target_mapping.csv"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `docs`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/source_to_target_mapping.csv`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\source_to_target_mapping.csv"` and require `True`.
4. Run `git status --short -- "docs/source_to_target_mapping.csv"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

[Back to the Phase 4 lesson index](#)

What your screen should look like now

- Every Phase 4 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 4.3 completion checklist

☐

`sql/sqlserver/source/01_create_erp_database.sql` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`sql/sqlserver/source/02_create_erp_tables.sql` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`sql/postgres/source/00_create_database.sql` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`sql/postgres/source/01_create_digital_schema.sql` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`docs/data_dictionary.csv` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`docs/source_to_target_mapping.csv` was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 4.4](#) and recheck the root and branch.

Lesson 4.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Source object 1 — `erp.product_categories`

Real-world object: `product_categories` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per category identifier. Verify that every column and example row describes that same unit.

Primary key: `category_id`

Foreign keys: `parent_category_id` → `product_categories.category_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>category_id</code>	INT	No	Yes	—	Category identifier	10	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>category_name</code>	NVARCHAR(100)	No	No	—	Business category name	Home Office	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>parent_category_id</code>	INT	Yes	No	<code>product_categories.category_id</code>	Optional parent category	NULL	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Nullable because the source can legitimately omit it
<code>created_at</code>	DATETIME2	No	No	—	Source creation timestamp	2026-01-02T10:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-02-03T11:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- category_id = 1
- category_name = Electronics
- parent_category_id = ``
- created_at = 2024-01-01T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S1 — Create and inspect `erp.product_categories`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.product_categories`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.product_categories` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.product_categories` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: `sql/sqlserver/source/02_create_erp_tables.sql`

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.product_categories
(
    category_id          INT NOT NULL CONSTRAINT PK_product_categories PRIMARY KEY,
    category_name        NVARCHAR(100) NOT NULL,
    parent_category_id   INT NULL,
    created_at           DATETIME2(3) NOT NULL,
    updated_at           DATETIME2(3) NOT NULL,
    CONSTRAINT FK_product_categories_parent FOREIGN KEY (parent_category_id)
```

);

Line-by-line DDL explanation

- **Line 1:** `CREATE TABLE erp.product_categories` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `erp.product_categories` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `( — (` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `category_id INT NOT NULL CONSTRAINT PK_product_categories PRIMARY KEY, —` `category_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PK_product_categories` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `category_name NVARCHAR(100) NOT NULL, —` `category_name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NVARCHAR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `100` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `parent_category_id INT NULL, —` `parent_category_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `created_at DATETIME2(3) NOT NULL, —` `created_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DATETIME2` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `updated_at DATETIME2(3) NOT NULL, —` `updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DATETIME2` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `CONSTRAINT FK_product_categories_parent FOREIGN KEY (parent_category_id) —` `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FK_product_categories_parent` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FOREIGN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `parent_category_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** `REFERENCES erp.product_categories(category_id) —` `REFERENCES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `erp.product_categories` is a name,

keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; category_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 10:**) ; —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S1.V — Verify metadata and row count for `erp.product_categories`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.product_categories;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.product_categories;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument,

identifier, or literal whose project-specific role is described in the surrounding explanation; FROM identifies the source table or query; `erp.product_categories` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.product_categories`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_product_categories_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.product_categories` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 2 — `erp.suppliers`

Real-world object: `suppliers` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per supplier identifier. Verify that every column and example row describes that same unit.

Primary key: `supplier_id`

Foreign keys: No foreign key; this object is a parent/reference table or independent event table.

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>supplier_id</code>	INT	No	Yes	—	Supplier identifier	501	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>supplier_code</code>	VARCHAR(20)	No	No	—	Supplier business key	SUP-0501	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>supplier_name</code>	NVARCHAR(150)	No	No	—	Fictional supplier name	Blue Harbor Goods	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>country_code</code>	CHAR(2)	No	No	—	ISO-like country code	US	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>lead_time_days</code>	INT	No	No	—	Expected replenishment lead time	14	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
active_flag	BIT	No	No	—	Whether supplier is active	1	a true/false flag. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2025-01-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-02-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- supplier_id = 5001
- supplier_code = SUP-05001
- supplier_name = Johnson Ltd Supply
- country_code = US
- lead_time_days = 14
- active_flag = 1
- created_at = 2024-01-01T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S2 — Create and inspect erp.suppliers

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect erp.suppliers. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.

3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.suppliers` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.suppliers` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.suppliers
(
    supplier_id      INT NOT NULL CONSTRAINT PK_suppliers PRIMARY KEY,
    supplier_code    VARCHAR(20) NOT NULL,
    supplier_name    NVARCHAR(150) NOT NULL,
    country_code     CHAR(2) NOT NULL,
    lead_time_days   INT NOT NULL,
    active_flag      BIT NOT NULL,
    created_at       DATETIME2(3) NOT NULL,
    updated_at       DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_suppliers_supplier_code UNIQUE (supplier_code),
    CONSTRAINT CK_suppliers_lead_time CHECK (lead_time_days >= 0)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE erp.suppliers — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.suppliers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** supplier_id INT NOT NULL CONSTRAINT PK_suppliers PRIMARY KEY, — supplier_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; INT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PK_suppliers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PRIMARY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 13:** `);` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S2.V — Verify metadata and row count for `erp.suppliers`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.suppliers;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.suppliers;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.suppliers` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.suppliers`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_suppliers_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.suppliers` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 3 — `erp.products`

Real-world object: products in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per product identifier. Verify that every column and example row describes that same unit.

Primary key: `product_id`

Foreign keys: `category_id` → `product_categories.category_id`; `supplier_id` → `suppliers.supplier_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
product_id	INT	No	Yes	—	Product identifier	10001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
sku	VARCHAR(30)	No	No	—	Stock keeping unit business key	NRT-ELE-10001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
product_name	NVARCHAR(200)	No	No	—	Product display name	Northstar Wireless Mouse	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
category_id	INT	No	No	product_categories.category_id	Product category	10	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
supplier_id	INT	No	No	suppliers.supplier_id	Primary supplier	501	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
brand	NVARCHAR(100)	No	No	—	Fictional brand	Aurora Works	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
unit_cost	DECIMAL(12,2)	No	No	—	Current source cost	18.50	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
list_price	DECIMAL(12,2)	No	No	—	Standard selling price	39.99	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
currency_code	CHAR(3)	No	No	—	Price currency	USD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
active_flag	BIT	No	No	—	Whether product is sellable	1	a true/false flag. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2025-01-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-02-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- product_id = 10001
- sku = NRT-OUT-10001
- product_name = Aurora Works Mat 1
- category_id = 5
- supplier_id = 5008
- brand = Cedar & Finch
- unit_cost = 22.77
- list_price = 37.63
- currency_code = USD
- active_flag = 1
- created_at = 2024-01-01T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S3 — Create and inspect erp.products

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.products`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.products` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.products` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.products
(
    product_id          INT NOT NULL CONSTRAINT PK_products PRIMARY KEY,
    sku                 VARCHAR(30) NOT NULL,
    product_name        NVARCHAR(200) NOT NULL,
    category_id         INT NOT NULL,
    supplier_id         INT NOT NULL,
    brand               NVARCHAR(100) NOT NULL,
    unit_cost           DECIMAL(12,2) NOT NULL,
    list_price          DECIMAL(12,2) NOT NULL,
    currency_code       CHAR(3) NOT NULL,
    active_flag         BIT NOT NULL,
    created_at          DATETIME2(3) NOT NULL,
    updated_at          DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_products_sku UNIQUE (sku),
    CONSTRAINT FK_products_category FOREIGN KEY (category_id) REFERENCES erp.product_categories(category_id),
    CONSTRAINT FK_products_supplier FOREIGN KEY (supplier_id) REFERENCES erp.suppliers(supplier_id),
    CONSTRAINT CK_products_amounts CHECK (unit_cost >= 0 AND list_price >= 0)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE erp.products — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.products is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S3.V — Verify metadata and row count for erp.products

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.products;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.products;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.products` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Interview-ready explanation

"I modeled `erp.products` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 4 — `erp.stores`

Real-world object: `stores` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per store identifier. Verify that every column and example row describes that same unit.

Primary key: `store_id`

Foreign keys: No foreign key; this object is a parent/reference table or independent event table.

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>store_id</code>	INT	No	Yes	—	Store identifier	201	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>store_code</code>	VARCHAR(20)	No	No	—	Store business key	VA-ARL-01	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>store_name</code>	NVARCHAR(150)	No	No	—	Store display name	Northstar Arlington	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>region</code>	VARCHAR(30)	No	No	—	Reporting region	Mid-Atlantic	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
state_code	CHAR(2)	No	No	—	US state code	VA	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
city	NVARCHAR(100)	No	No	—	Store city	Arlington	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
open_date	DATE	No	No	—	Store opening date	2021-05-01	a calendar date with no time-of-day component. Required because the business record is incomplete without it
active_flag	BIT	No	No	—	Whether store is open	1	a true/false flag. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2021-05-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-02-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- store_id = 201
- store_code = NY-NEW-01
- store_name = Northstar New York 1
- region = Northeast
- state_code = NY
- city = New York
- open_date = 2023-09-01
- active_flag = 1
- created_at = 2024-01-01T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S4 — Create and inspect erp.stores

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.stores`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.stores` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.stores` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.stores
(
    store_id          INT NOT NULL CONSTRAINT PK_stores PRIMARY KEY,
    store_code        VARCHAR(20) NOT NULL,
    store_name        NVARCHAR(150) NOT NULL,
    region            VARCHAR(30) NOT NULL,
    state_code        CHAR(2) NOT NULL,
    city              NVARCHAR(100) NOT NULL,
    open_date         DATE NOT NULL,
    active_flag       BIT NOT NULL,
    created_at        DATETIME2(3) NOT NULL,
    updated_at        DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_stores_store_code UNIQUE (store_code)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE erp.stores — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.stores is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** store_id INT NOT NULL CONSTRAINT PK_stores PRIMARY KEY, — store_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; INT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PK_stores is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PRIMARY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- [illegible]

- **Line 12:** `updated_at DATETIME2(3) NOT NULL`, — `updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DATETIME2` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 13:** `CONSTRAINT UQ_stores_store_code UNIQUE (store_code)` — `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `UQ_stores_store_code` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `UNIQUE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `store_code` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 14:** `);` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S4.V — Verify metadata and row count for `erp.stores`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.stores;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.stores;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.stores` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.

- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.stores`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_stores_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.stores` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 5 — `erp.employees`

Real-world object: `employees` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per employee identifier. Verify that every column and example row describes that same unit.

Primary key: `employee_id`

Foreign keys: `store_id` → `stores.store_id`; `manager_employee_id` → `employees.employee_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>employee_id</code>	INT	No	Yes	—	Employee identifier	301	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>employee_number</code>	VARCHAR(20)	No	No	—	Employee business key	EMP-00301	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>store_id</code>	INT	Yes	No	<code>stores.store_id</code>	Assigned store	201	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Nullable because the source can legitimately omit it
<code>manager_employee_id</code>	INT	Yes	No	<code>employees.employee_id</code>	Manager identifier	300	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Nullable because the source can legitimately omit it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
first_name	NVARCHAR(80)	No	No	—	Synthetic first name	Mina	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
last_name	NVARCHAR(80)	No	No	—	Synthetic last name	Nassar	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
job_title	NVARCHAR(100)	No	No	—	Job title	Sales Associate	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
hire_date	DATE	No	No	—	Hire date	2024-03-11	a calendar date with no time-of-day component. Required because the business record is incomplete without it
active_flag	BIT	No	No	—	Employment status	1	a true/false flag. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2024-03-11T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-02-01T00:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- employee_id = 301
- employee_number = EMP-00301
- store_id = 201
- manager_employee_id = ``
- first_name = Alexis
- last_name = Clark
- job_title = Store Manager

- hire_date = 2023-02-12
- active_flag = 1
- created_at = 2024-01-01T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S5 — Create and inspect `erp.employees`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.employees`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.employees` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.employees` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.

10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.employees
(
    employee_id          INT NOT NULL CONSTRAINT PK_employees PRIMARY KEY,
    employee_number      VARCHAR(20) NOT NULL,
    store_id             INT NULL,
    manager_employee_id  INT NULL,
    first_name           NVARCHAR(80) NOT NULL,
    last_name            NVARCHAR(80) NOT NULL,
    job_title            NVARCHAR(100) NOT NULL,
    hire_date            DATE NOT NULL,
    active_flag          BIT NOT NULL,
    created_at           DATETIME2(3) NOT NULL,
    updated_at           DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_employees_number UNIQUE (employee_number),
    CONSTRAINT FK_employees_store FOREIGN KEY (store_id) REFERENCES erp.stores(store_id),
    CONSTRAINT FK_employees_manager FOREIGN KEY (manager_employee_id) REFERENCES erp.employees(employee_id)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE erp.employees — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.employees is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- [illegible]

- **Line 17:** `) ; — )` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S5.V — Verify metadata and row count for `erp.employees`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.employees;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.employees;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.employees` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.employees`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_employees_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.employees` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 6 — `erp.customers`

Real-world object: customers in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per customer identifier. Verify that every column and example row describes that same unit.

Primary key: `customer_id`

Foreign keys: No foreign key; this object is a parent/reference table or independent event table.

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>customer_id</code>	INT	No	Yes	—	Customer identifier	100001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>customer_number</code>	VARCHAR(25)	No	No	—	Customer business key; dirty duplicates are intentional	CUS-100001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>first_name</code>	NVARCHAR(80)	No	No	—	Synthetic first name	Amanuel	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>last_name</code>	NVARCHAR(80)	No	No	—	Synthetic last name	Gebre	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>email</code>	NVARCHAR(255)	Yes	No	—	Synthetic email; may contain controlled issues	amanuel@example.test	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
<code>phone</code>	VARCHAR(40)	Yes	No	—	Synthetic phone	+1-555-0100	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
signup_date	DATE	No	No	—	Customer signup date	2025-06-12	a calendar date with no time-of-day component. Required because the business record is incomplete without it
loyalty_tier	VARCHAR(20)	No	No	—	Loyalty segment	Silver	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
marketing_opt_in	BIT	No	No	—	Marketing consent flag	1	a true/false flag. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2025-06-12T12:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-01-05T12:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- customer_id = 100001
- customer_number = CUS-0100001
- first_name = Andrew
- last_name = Hayes
- email = ``
- phone = +1-555-7736
- signup_date = 2025-10-26
- loyalty_tier = Bronze
- marketing_opt_in = 1
- created_at = 2025-10-26T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S6 — Create and inspect erp.customers

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.customers`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.customers` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.customers` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.customers
(
    customer_id          INT NOT NULL CONSTRAINT PK_customers PRIMARY KEY,
    customer_number      VARCHAR(25) NOT NULL,
    first_name           NVARCHAR(80) NOT NULL,
    last_name            NVARCHAR(80) NOT NULL,
    email                NVARCHAR(255) NULL,
    phone                VARCHAR(40) NULL,
    signup_date          DATE NOT NULL,
    loyalty_tier          VARCHAR(20) NOT NULL,
    marketing_opt_in     BIT NOT NULL,
    created_at           DATETIME2(3) NOT NULL,
    updated_at           DATETIME2(3) NOT NULL
    -- Deliberately no unique constraint on customer_number in the learning source:
    -- controlled duplicate business keys must reach Silver and be handled there.
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE erp.customers — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.customers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** customer_id INT NOT NULL CONSTRAINT PK_customers PRIMARY KEY, — customer_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; INT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PK_customers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PRIMARY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** customer_number VARCHAR(25) NOT NULL, — customer_number is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; VARCHAR is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 25 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

ifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- [illegible]

- **Line 13:** updated_at DATETIME2(3) NOT NULL — updated_at is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; DATETIME2 is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 3 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 14:** -- Deliberately no unique constraint on customer_number in the learning source: is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 15:** -- controlled duplicate business keys must reach Silver and be handled there. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 16:**) ; —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S6.V — Verify metadata and row count for erp.customers

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.customers;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.customers;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.customers` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.

- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.customers`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_customers_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.customers` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 7 — `erp.addresses`

Real-world object: addresses in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per address identifier. Verify that every column and example row describes that same unit.

Primary key: `address_id`

Foreign keys: `customer_id` → `customers.customer_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>address_id</code>	INT	No	Yes	—	Address identifier	500001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>customer_id</code>	INT	No	No	<code>customers.customer_id</code>	Owning customer	100001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>address_type</code>	VARCHAR(20)	No	No	—	Billing or shipping	Shipping	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
<code>line1</code>	NVARCHAR(200)	No	No	—	Synthetic street line	123 Example Ave	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
line2	NVARCHAR(200)	Yes	No	—	Optional unit	Apt 4	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
city	NVARCHAR(100)	No	No	—	City	Richmond	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
state_code	VARCHAR(10)	No	No	—	State code; controlled invalid values included	VA	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
postal_code	VARCHAR(20)	No	No	—	Postal code	23220	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
country_code	VARCHAR(10)	No	No	—	Country code	US	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
is_default	BIT	No	No	—	Default address flag	1	a true/false flag. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2025-06-12T12:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-01-05T12:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- address_id = 500001
- customer_id = 100001
- address_type = Shipping
- line1 = 643 Hammond Shoals
- line2 = ``
- city = San Diego
- state_code = VIRGINIA
- postal_code = 51556
- country_code = US
- is_default = 1
- created_at = 2025-10-26T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S7 — Create and inspect erp.addresses

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect erp.addresses. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/sqlserver/source/02_create_erp_tables.sql in VS Code beside the database editor.
4. TYPE THIS: Build the erp.addresses definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.

2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/sqlserver/source/02_create_erp_tables.sql in VS Code beside the database editor.
4. TYPE THIS: Build the erp.addresses definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.addresses
(
    address_id          INT NOT NULL CONSTRAINT PK_addresses PRIMARY KEY,
    customer_id         INT NOT NULL,
    address_type        VARCHAR(20) NOT NULL,
    line1               NVARCHAR(200) NOT NULL,
    line2               NVARCHAR(200) NULL,
    city                NVARCHAR(100) NOT NULL,
    state_code          VARCHAR(10) NOT NULL,
    postal_code         VARCHAR(20) NOT NULL,
    country_code        VARCHAR(10) NOT NULL,
    is_default          BIT NOT NULL,
    created_at          DATETIME2(3) NOT NULL,
    updated_at          DATETIME2(3) NOT NULL,
```

```
CONSTRAINT FK_addresses_customer FOREIGN KEY (customer_id) REFERENCES erp.customers(customer_id)
);
```

Line-by-line DDL explanation

- **Line 1:** `CREATE TABLE erp.addresses` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `erp.addresses` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `address_id INT NOT NULL CONSTRAINT PK_addresses PRIMARY KEY,` — `address_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PK_addresses` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `customer_id INT NOT NULL,` — `customer_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `address_type VARCHAR(20) NOT NULL,` — `address_type` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `VARCHAR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `20` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `line1 NVARCHAR(200) NOT NULL,` — `line1` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NVARCHAR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `200` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `line2 NVARCHAR(200) NULL,` — `line2` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NVARCHAR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `200` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `city NVARCHAR(100) NOT NULL,` — `city` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NVARCHAR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `100` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- [illegible]

Verification query

Action 4.4.S7.V — Verify metadata and row count for erp.addresses

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.addresses;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.addresses;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.addresses` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.addresses`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_addresses_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.addresses` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 8 — `erp.orders`

Real-world object: orders in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to

SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per order identifier. Verify that every column and example row describes that same unit.

Primary key: order_id

Foreign keys: customer_id → customers.customer_id; store_id → stores.store_id; employee_id → employees.employee_id

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
order_id	BIGINT	No	Yes	—	Order identifier	9000001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
order_number	VARCHAR(30)	No	No	—	Order business key	ORD-09000001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
customer_id	INT	No	No	customers.customer_id	Ordering customer	100001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
store_id	INT	Yes	No	stores.store_id	Store for store sales or fulfillment	201	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Nullable because the source can legitimately omit it
employee_id	INT	Yes	No	employees.employee_id	Sales employee when applicable	301	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Nullable because the source can legitimately omit it
channel_code	VARCHAR(20)	No	No	—	STORE or ONLINE	ONLINE	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
order_timestamp	DATETIME2	No	No	—	Order event time	2026-01-04T14:22:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
order_status	VARCHAR(20)	No	No	—	Operational order status	SHIPPED	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
promotion_code	VARCHAR(30)	Yes	No	—	Promotion business key	WINTER10	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
currency_code	CHAR(3)	No	No	—	Order currency	USD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
subtotal_amount	DECIMAL(14,2)	No	No	—	Pre-tax and pre-shipping amount after item discounts	99.98	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
tax_amount	DECIMAL(14,2)	No	No	—	Tax amount	6.00	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
shipping_amount	DECIMAL(14,2)	No	No	—	Shipping charge	5.99	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
order_total_amount	DECIMAL(14,2)	No	No	—	Customer charged total	111.97	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2026-01-04T14:22:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-01-05T10:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- order_id = 9000001
- order_number = ORD-009000001
- customer_id = 100050
- store_id = 204
- employee_id = 309.0
- channel_code = STORE
- order_timestamp = 2026-06-25T14:48:00
- order_status = COMPLETED
- promotion_code = WELCOME10
- currency_code = USD
- created_at = 2026-06-25T14:48:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S8 — Create and inspect erp.orders

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect `erp.orders`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to `master`, `postgres`, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.orders` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to `master`, `postgres`, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.orders` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Verification query

Action 4.4.S8.V — Verify metadata and row count for `erp.orders`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.orders;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.orders;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.orders` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.

- **If the object matches exactly and was created by your verified earlier run:** Record VERIFIED BY USER and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.orders`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_orders_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.orders` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 9 — `erp.order_items`

Real-world object: `order_items` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per sales-line identifier. Verify that every column and example row describes that same unit.

Primary key: `order_item_id`

Foreign keys: `order_id` → `orders.order_id`; `product_id` → `products.product_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>order_item_id</code>	BIGINT	No	Yes	—	Sales-line identifier	9100001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
<code>order_id</code>	BIGINT	No	No	<code>orders.order_id</code>	Parent order	9000001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
<code>line_number</code>	INT	No	No	—	Line sequence within order	1	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
product_id	INT	No	No	products.product_id	Sold product	10001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
quantity	INT	No	No	—	Units ordered; controlled impossible values included	2	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
unit_price	DECIMAL(12,2)	No	No	—	Price per unit before discount	39.99	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
discount_amount	DECIMAL(12,2)	No	No	—	Line discount	4.00	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
tax_amount	DECIMAL(12,2)	No	No	—	Allocated line tax	4.56	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
unit_cost	DECIMAL(12,2)	No	No	—	Cost per unit at sale	18.50	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
line_total_amount	DECIMAL(14,2)	No	No	—	Quantity times unit price minus discount	75.98	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2026-01-04T14:22:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-01-04T14:22:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- order_item_id = 10000001
- order_id = 9000001
- line_number = 1
- product_id = 10026
- quantity = -2
- unit_price = 17.69
- unit_cost = 11.26
- discount_amount = 1.77
- tax_amount = 1.68
- created_at = 2026-06-25T14:48:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S9 — Create and inspect erp.order_items

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect erp.order_items. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.order_items` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.order_items` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.order_items
(
    order_item_id    BIGINT NOT NULL CONSTRAINT PK_order_items PRIMARY KEY,
    order_id         BIGINT NOT NULL,
    line_number      INT NOT NULL,
    product_id       INT NOT NULL,
    quantity         INT NOT NULL,
    unit_price       DECIMAL(12,2) NOT NULL,
    unit_cost        DECIMAL(12,2) NOT NULL,
    discount_amount  DECIMAL(12,2) NOT NULL,
    tax_amount       DECIMAL(12,2) NOT NULL,
    created_at       DATETIME2(3) NOT NULL,
    updated_at       DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_order_items_line UNIQUE (order_id, line_number),
    CONSTRAINT FK_order_items_order FOREIGN KEY (order_id) REFERENCES erp.orders(order_id),
    CONSTRAINT FK_order_items_product FOREIGN KEY (product_id) REFERENCES erp.products(product_id)
    -- No positive-quantity check: controlled impossible quantities are a Silver lesson.
);
```

Line-by-line DDL explanation

- **Line 1:** `CREATE TABLE erp.order_items` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `erp.order_items` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 14:** CONSTRAINT UQ_order_items_line UNIQUE (order_id, line_number), — CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; UQ_order_items_line is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; UNIQUE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; order_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; line_number is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 15:** CONSTRAINT FK_order_items_order FOREIGN KEY (order_id) REFERENCES erp.orders(order_id), — CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FK_order_items_order is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FOREIGN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; order_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; REFERENCES is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; erp.orders is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; order_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 16:** CONSTRAINT FK_order_items_product FOREIGN KEY (product_id) REFERENCES erp.products(product_id) — CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FK_order_items_product is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FOREIGN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; product_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; REFERENCES is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; erp.products is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; product_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 17:** -- No positive-quantity check: controlled impossible quantities are a Silver lesson. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 18:**); —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S9.V — Verify metadata and row count for erp.order_items

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.order_items;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.order_items;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.order_items` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.order_items`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_order_items_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.order_items` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 10 — `erp.payments`

Real-world object: payments in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per payment identifier. Verify that every column and example row describes that same unit.

Primary key: `payment_id`

Foreign keys: `order_id` → `orders.order_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
payment_id	BIGINT	No	Yes	—	Payment identifier	9200001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
order_id	BIGINT	No	No	orders.order_id	Paid order	9000001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
payment_timestamp	DATETIME2	No	No	—	Payment event time	2026-01-04T14:23:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
payment_method	VARCHAR(30)	No	No	—	Card, wallet, gift card, or cash	CARD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
payment_status	VARCHAR(20)	No	No	—	Payment status	CAPTURED	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
amount	DECIMAL(14,2)	No	No	—	Payment amount	111.97	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
currency_code	CHAR(3)	No	No	—	Payment currency	USD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
transaction_reference	VARCHAR(80)	No	No	—	Fictional processor reference	PAY-ABC123	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2026-01-04T14:23:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-01-04T14:23:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- payment_id = 20000001
- order_id = 90000001
- payment_timestamp = 2026-06-25T14:54:00
- payment_method = CARD
- payment_status = CAPTURED
- amount = 35.29
- currency_code = usd
- transaction_reference = PAY-5E01CF81A39CE7B9
- created_at = 2026-06-25T14:48:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S10 — Create and inspect erp.payments

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect erp.payments. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.payments` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.payments` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.payments
(
    payment_id          BIGINT NOT NULL CONSTRAINT PK_payments PRIMARY KEY,
    order_id            BIGINT NOT NULL,
    payment_timestamp   DATETIME2(3) NOT NULL,
    payment_method      VARCHAR(30) NOT NULL,
    payment_status      VARCHAR(30) NOT NULL,
    amount              DECIMAL(14,2) NOT NULL,
    currency_code       VARCHAR(3) NOT NULL,
    transaction_reference VARCHAR(80) NOT NULL,
    created_at          DATETIME2(3) NOT NULL,
    updated_at          DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_payments_transaction UNIQUE (transaction_reference),
    CONSTRAINT FK_payments_order FOREIGN KEY (order_id) REFERENCES erp.orders(order_id)
);
```

Line-by-line DDL explanation

- Line 1:** `CREATE TABLE erp.payments` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `erp.payments` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 3:** `payment_id BIGINT NOT NULL CONSTRAINT PK_payments PRIMARY KEY,` — `payment_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BIGINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PK_payments` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 4:** `order_id BIGINT NOT NULL,` — `order_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BIGINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 5:** `payment_timestamp DATETIME2(3) NOT NULL,` — `payment_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DATETIME2` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 6:** `payment_method VARCHAR(30) NOT NULL,` — `payment_method` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `VARCHAR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `30` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is

described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

literal whose project-specific role is described in the surrounding explanation;) , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
