Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 10 lesson index](#)

Action 10.5.G7 — Create the Phase 10 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: conform and quarantine silver entities"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: conform and quarantine silver entities"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: conform and quarantine silver entities"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 10 lesson index](#)

Action 10.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command op-

tion or flag; its exact behavior is defined beside the command; --oneLine is a command option or flag; its exact behavior is defined beside the command; --decorate is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 10 lesson index](#)

Action 10.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 10 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: conform and quarantine silver entities` and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 10.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 10 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 10 created the verified boundary described by **Build the Silver cleaning and conformance layer**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

Mini quiz

1. Multiple choice: Why does Phase 10 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** PLANNED, CREATED BY USER, and RUN BY USER describe earlier states; only inspected evidence supports verification.

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 10.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 11 converts descriptive entities into durable dimensions.

Phase 10 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 11 — Build Gold dimensions, surrogate keys, and SCD behavior

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Verified dimensions with unknown rows and effective dates.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 12 resolves dimension keys while building facts at declared grains.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 11 lesson index

1. [Lesson 11.1 — Understand the phase and starting screen](#)
2. [Lesson 11.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 11.3 — Create and understand the phase files](#)
4. [Lesson 11.4 — Build and validate required objects](#)
5. [Lesson 11.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 11.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Databricks notebooks, Catalog Explorer, and SQL/Python cells.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.

- **Files that should not exist yet:** New Phase 11 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 10 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 11 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Databricks notebooks, Catalog Explorer, and SQL/Python cells. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 11 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 11 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 11 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 11.1 completion checklist

☐

I read why Phase 11 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 11.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 11 lesson index](#)

Lesson 11.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 11 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required
Ownership status at start: Workbook instructions exist; your execution is not yet verified.
Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

Nine business dimensions: date, customer, product, store, employee, supplier, promotion, channel, and campaign. Customer/product preserve selected history with SCD Type 2; other dimensions use Type 1 where appropriate. Every dimension has a surrogate key, natural key, audit fields, and an unknown row.

2. Why it matters

Dimensions provide consistent descriptive context across facts. Surrogate keys separate warehouse identity from source identifiers; SCD2 preserves historical truth; unknown rows let facts load while unresolved context remains measurable.

3. Words to know

Term	Plain-language definition
Dimension grain	One row per current entity or per historical entity version.
Natural key	Business identifier from source, such as SKU.
Surrogate key	Warehouse key used by facts.
SCD Type 1	Overwrite correction; no prior version retained.
SCD Type 2	Expire old row and insert new effective-dated version.
Effective start/end	Date range when a dimension version is valid.
Current flag	Boolean marking open current version.
Tracked attribute	Column whose change creates a new Type 2 version.
Record hash	Hash of tracked attributes used to detect change.
Unknown member	Key 0 row for missing/invalid/late context.
Inferred member	Minimal placeholder created for a known natural key before full attributes arrive.
Overlap	Two versions valid for same key/date; invalid SCD state.
Event-time lookup	Fact joins the dimension version valid when event happened.

4. What must already be completed

Relevant Silver tables pass and natural keys are stable/unique. Date range requirements and Type 1/2 attribute decisions are documented.

5. Applications to open

Application	How to open it	Why it is open
Databricks notebook 08	Workspace.	Build dimensions and complete user-owned patterns.
Catalog Explorer / SQL editor	Gold schema.	Inspect keys/history/unknown rows.
VS Code	Notebook source, SCD SQL pattern, data dictionary.	Review implementation and tracked columns.
SCD diagram	docs/images/scd2_timeline.svg.	Explain version behavior visually.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
SELECT customer_number, COUNT(*) AS versions,	Finds keys with history and invalid current counts.	SCD2 must have exactly one current row; history itself is expected.
SELECT a.customer_number, a.customer_key AS a_key, b.customer_key AS b_key,	Detects overlapping SCD2 date ranges.	Overlap makes event-time lookup ambiguous.
SELECT 'dim_customer' AS table_name, COUNT(*) AS unknown_rows FROM northstar_retail.gold.dim_customer WHERE customer_key=0	Checks required unknown rows.	Fact foreign keys need a governed fallback.
version_key = (F.abs(F.xxhash64(F.concat_ws(" ", F.col(business_key), F.col("record_hash")))) + F.lit(1)).cast("long")	Creates deterministic surrogate key from natural key plus version hash.	Different historical versions must not reuse one key.

SCD2 worked example

Customer CUS-100001 is Silver tier from 2026-01-01 through 2026-05-31. On 2026-06-01 the source reports Gold. The old row remains with current false/end 2026-05-31; a new surrogate row starts 2026-06-01 and ends 9999-12-31/current true. A May sale joins Silver version; a July sale joins Gold version.

Full refresh versus incremental

`dim_date` can be regenerated deterministically. Small static channel mappings can be full-replaced in development. SCD2 dimensions require incremental change processing or carefully reconstructed full history; blindly overwriting loses version lineage.

MY TASK

Fix/complete version-specific surrogate key generation, add unknown members for all dimensions, run one controlled SCD2 change, and produce a dimension audit matrix with grain, SCD type, natural key, tracked fields, unknown policy, and tests.

STARTER SKELETON

```
def add_unknown_member(df, schema):
    # TODO(USER): create one row matching schema with key 0 and safe labels.
    unknown = spark.createDataFrame([_____], schema=schema)
    return unknown.unionByName(df)

def scd2_version_key(business_key: str):
    # TODO(USER): combine natural key with record_hash so versions differ.
    return (F.abs(F.xxhash64(F.concat_ws("||", F.col(business_key), _____))) + 1).cast("long")

# TODO(USER): MERGE unknown row once and test exactly one row with key 0.
```

Acceptance criteria: All nine dimensions exist; natural/surrogate keys and grains are valid; every dimension has one unknown row; controlled SCD2 change creates non-overlapping versions and unique keys; rerun does not duplicate current rows.

HINT 1 — CONCEPT

A Type 2 surrogate key identifies a version, not only an entity.

HINT 2 — PSEUDOCODE

Hash tracked fields first, then combine business key and record hash for deterministic version key.

HINT 3 — NEAR-COMPLETE PATTERN

Copy the SQL Server warehouse unknown-row values or data dictionary to build one schema-compatible row per dimension.

13. Expected files or output

- 9 Gold dimensions.
- Unknown key 0 in each.
- Customer/product history fields.
- One controlled multi-version example.
- Dimension audit/test matrix.
- Stable rerun results.

14. How to verify

- Unique surrogate keys.
- One current version/natural key.
- No overlaps/gaps policy documented.
- Unknown exactly once.
- Tracked-change creates new key/version; untracked correction follows stated Type 1/no-change behavior.
- Date dimension covers source event range.

15. Automated tests

- Surrogate and natural/current uniqueness.
- SCD overlap/current-count tests.
- Record hash change/no-change tests.
- Unknown member tests.
- Type 1 rerun tests.
- Date completeness/uniqueness.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
Duplicate surrogate key after SCD change	Key derived only from business key.	Group by surrogate key and inspect hashes/versions.	Derive version key from business key + record hash/version start.	Unique test passes.
Multiple current rows	Merge inserted changed row without expiring old or rerun duplicate.	Query current count per business key.	Expire matching current once; insert changed once; idempotent staging.	Exactly one current.
Date ranges overlap	End/start logic wrong or multiple changes same date.	Overlap self-join query.	Define date/timestamp granularity; end old before new; handle same-day changes.	Zero overlaps.
Unknown row duplicated	Unknown append on every run.	Count key 0.	MERGE/insert-if-not-exists or deterministic full replacement.	Exactly one.
Facts later map all to unknown	Natural keys absent/mismatched case or event-time condition.	Compare Silver natural keys to dimensions.	Standardize same codes and test lookup match rate before facts.	Unknown rate within threshold.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why can one customer have multiple surrogate keys?
2. What determines tracked attributes?
3. What is wrong with overlapping SCD date ranges?
4. When would you use unknown versus inferred member?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What two inputs should a deterministic SCD2 version key include?
2. How many current rows should one business key have?
3. Why must fact lookup include event date?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture one controlled customer/product history with old/new keys/dates/current flags, plus unknown-member and overlap test results.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: build gold dimensions with scd2 and unknown members
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

All dimension grains stated — [STATUS]

☐

Type 1 dimensions verified — [STATUS]

☐

Customer/product SCD2 verified — [STATUS]

☐

Version keys unique — [STATUS]

☐

Unknown rows complete — [STATUS]

☐

Overlap/current tests pass — [STATUS]

☐

Late-arriving policy documented — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-11. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-11.

Next phase: Phase 12 resolves those dimensions into six facts and validates additive/non-additive measures.

Required action cards

Action 11.2.1 — Use a toy employee department example: Type 1 fixes a misspelling; Type 2 preserves a department transfer. Dec

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Use a toy employee department example: Type 1 fixes a misspelling; Type 2 preserves a department transfer. Dec. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Use a toy employee department example: Type 1 fixes a misspelling; Type 2 preserves a department transfer. Decide which question requires history before reading final code.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Use a toy employee department example: Type 1 fixes a misspelling; Type 2 preserves a department transfer. Decide which question requires history before reading final code.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 11 lesson index](#)

Action 11.2.2 — State each dimension grain. `dim_customer` and `dim_product`: one row per natural key per effective historical

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

State each dimension grain. `dim_customer` and `dim_product`: one row per natural key per effective historical. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: State each dimension grain. `dim_customer` and `dim_product`: one row per natural key per effective historical version. Type 1 dimensions: one row per natural key.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

State each dimension grain. `dim_customer` and `dim_product`: one row per natural key per effective historical version. Type 1 dimensions: one row per natural key.

Before continuing☐

I used the application named in this phase.

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 11 lesson index](#)

Action 11.2.8 — Run SCD2 initial load. Insert unknown row key 0 into every dimension using a rerun-safe MERGE/union policy.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run SCD2 initial load. Insert unknown row key 0 into every dimension using a rerun-safe MERGE/union policy. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Run SCD2 initial load. Insert unknown row key 0 into every dimension using a rerun-safe MERGE/union policy.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 8

Action

Run SCD2 initial load. Insert unknown row key 0 into every dimension using a rerun-safe MERGE/union policy.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 11 lesson index](#)

Action 11.2.9 — Create a controlled SCD2 test: in a copied Silver test row, change one tracked customer tier or product cost,

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Create a controlled SCD2 test: in a copied Silver test row, change one tracked customer tier or product cost, . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Create a controlled SCD2 test: in a copied Silver test row, change one tracked customer tier or product cost, run a new batch/date, and verify old row expires and new row starts without overlap.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 9****Action**

Create a controlled SCD2 test: in a copied Silver test row, change one tracked customer tier or product cost, run a new batch/date, and verify old row expires and new row starts without overlap.

Before continuing☐

I used the application named in this phase.

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 11 lesson index](#)

Action 11.2.C1 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT customer_number, COUNT(*) AS versions,
       SUM(CASE WHEN is_current THEN 1 ELSE 0 END) AS current_versions
FROM northstar_retail.gold.dim_customer
GROUP BY customer_number
HAVING current_versions <> 1 OR versions > 1
ORDER BY versions DESC;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT customer_number, COUNT(*) AS versions,` — `SELECT` requests data without changing it unless combined with a modifying statement; `customer_number` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `versions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `SUM(CASE WHEN is_current THEN 1 ELSE 0 END) AS current_versions` — `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `CASE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `is_current` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `1` is a numeric literal used by the command or expression; `ELSE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `0` is a numeric literal used by the command or expression; `END` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 3:** `FROM northstar_retail.gold.dim_customer` — `FROM` identifies the source table or query; `northstar_retail.gold.dim_customer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `GROUP BY customer_number` — `GROUP` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `customer_number` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `HAVING current_versions <> 1 OR versions > 1` — `HAVING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_versions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `<>` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `1` is a numeric literal used by the command or expression; `OR` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `versions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `1` is a numeric literal used by the command or expression
- **Line 6:** `ORDER BY versions DESC;` — `ORDER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `versions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DESC` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.2.C2 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.

2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT a.customer_number, a.customer_key AS a_key, b.customer_key AS b_key,
       a.effective_start_date, a.effective_end_date,
       b.effective_start_date, b.effective_end_date
FROM northstar_retail.gold.dim_customer a
JOIN northstar_retail.gold.dim_customer b
  ON a.customer_number=b.customer_number
 AND a.customer_key < b.customer_key
 AND a.effective_start_date <= b.effective_end_date
 AND b.effective_start_date <= a.effective_end_date;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT a.customer_number, a.customer_key AS a_key, b.customer_key AS b_key,` — `SELECT` requests data without changing it unless combined with a modifying statement; `a.customer_number` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a.customer_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `b.customer_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `b_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `a.effective_start_date, a.effective_end_date,` — `a.effective_start_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a.effective_end_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 4:** `FROM northstar_retail.gold.dim_customer a` — `FROM` identifies the source table or query; `northstar_retail.gold.dim_customer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `JOIN northstar_retail.gold.dim_customer b` — `JOIN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_retail.gold.dim_customer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;

b is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 6:** `ON a.customer_number=b.customer_number` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a.customer_number` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `b.customer_number` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `AND a.customer_key < b.customer_key` — `AND` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a.customer_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `b.customer_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `AND a.effective_start_date <= b.effective_end_date` — `AND` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a.effective_start_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `<=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `b.effective_end_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** `AND b.effective_start_date <= a.effective_end_date;` — `AND` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `b.effective_start_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `<=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `a.effective_end_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.2.C3 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT 'dim_customer' AS table_name, COUNT(*) AS unknown_rows FROM northstar_retail.gold.dim_customer WHERE customer_key=0
UNION ALL SELECT 'dim_product', COUNT(*) FROM northstar_retail.gold.dim_product WHERE product_key=0
UNION ALL SELECT 'dim_store', COUNT(*) FROM northstar_retail.gold.dim_store WHERE store_key=0;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT 'dim_customer' AS table_name, COUNT(*) AS unknown_rows FROM northstar_retail.gold.dim_customer WHERE customer_key=0 — SELECT requests data without changing it unless combined with a modifying statement; 'dim_customer' is a quoted literal; the quotation marks preserve spaces or mark text; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; table_name is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal

whose project-specific role is described in the surrounding explanation; unknown_rows is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FROM identifies the source table or query; northstar_retail.gold.dim_customer is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHERE filters rows to those meeting a condition; remaining punctuation and identifiers continue the same statement.

- **Line 2:** UNION ALL SELECT 'dim_product', COUNT(*) FROM northstar_retail.gold.dim_product WHERE product_key=0 — UNION is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; ALL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SELECT requests data without changing it unless combined with a modifying statement; 'dim_product' is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FROM identifies the source table or query; northstar_retail.gold.dim_product is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHERE filters rows to those meeting a condition; product_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 3:** UNION ALL SELECT 'dim_store', COUNT(*) FROM northstar_retail.gold.dim_store WHERE store_key=0; — UNION is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; ALL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SELECT requests data without changing it unless combined with a modifying statement; 'dim_store' is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FROM identifies the source table or query; northstar_retail.gold.dim_store is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHERE filters rows to those meeting a condition; store_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.2.C4 — Databricks notebook cell

Application:

Databricks workspace in a web browser

Window or panel:

Databricks notebook cell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Python instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Python):

```
version_key = (F.abs(F.xxhash64(F.concat_ws("||", F.col("business_key"), F.col("record_hash")))) + F.lit(1)).cast("long")
```

Where to enter it:

Databricks notebook cell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `version_key = (F.abs(F.xxhash64(F.concat_ws("||", F.col("business_key"), F.col("record_hash")))) + F.lit(1)).cast("long")` — `version_key` is a name, keyword, argument, identifier, or literal whose project-specific role

is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; F.abs is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; F.xxhash64 is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; F.concat_ws is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; " | | " is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; F.col is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 11.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 11 starting-screen checklist and re-verify the active context.

Lesson 11.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 11 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — databricks/

Exact folder name: databricks

Exact parent: repository root

Why it is needed now: Phase 11 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: databricks.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 11.D1.1 — Create the folder databricks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\databricks" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\databricks" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\databricks" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/

Exact folder name: `sql`

Exact parent: `repository root`

Why it is needed now: Phase 11 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `repository root` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `sql`.
7. PRESS: Enter.

8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 11.D2.1 — Create the folder sql

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — databricks/notebooks/

Exact folder name: `notebooks`

Exact parent: `databricks`

Why it is needed now: Phase 11 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path databricks one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: notebooks.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 11.D3.1 — Create the folder databricks/notebooks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks\notebooks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks\notebooks" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\notebooks"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql\databricks\gold" -PathType Container` and require True.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\databricks\gold" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\databricks\gold" -PathType Container`.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — databricks/notebooks/08_gold_dimensions.py

Exact filename: `08_gold_dimensions.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `databricks/notebooks` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 11.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `databricks/notebooks` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.

6. CLICK: Select **New File**.
7. TYPE THIS: `08_gold_dimensions.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `08_gold_dimensions.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 11.F1.1 — Create the file `databricks/notebooks/08_gold_dimensions.py` from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\databricks\notebooks\08_gold_dimensions.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\databricks\notebooks\08_gold_dimensions.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\notebooks\08_gold_dimensions.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\databricks\notebooks\08_gold_dimensions.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "databricks/notebooks/08_gold_dimensions.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.

5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under databricks/notebooks.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with databricks/notebooks/08_gold_dimensions.py.
3. In PowerShell at the repository root, run Test-Path ".\databricks\notebooks\08_gold_dimensions.py" and require True.
4. Run git status --short -- "databricks/notebooks/08_gold_dimensions.py" to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for databricks/notebooks/08_gold_dimensions.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: databricks/notebooks/08_gold_dimensions.py

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 11.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Databricks notebook source
# Northstar Retail End-to-End Data Platform
# This file is a Git-friendly Databricks source notebook.
# Track A reads files that you manually uploaded to a Unity Catalog volume.
# It never attempts to reach SQL Server or PostgreSQL on localhost.

# COMMAND -----
# MAGIC %md
# MAGIC # 08 – Gold dimensions
# MAGIC Builds unknown rows, Type 1 dimensions, and SCD Type 2 customer/product dimensions.

File introduction — sql/databricks/gold/01_scd2_merge_pattern.sql

Exact filename: 01_scd2_merge_pattern.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/databricks/gold relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 11.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/databricks/gold one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 01_scd2_merge_pattern.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 01_scd2_merge_pattern.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 11.F2.1 — Create the file sql/databricks/gold/01_scd2_merge_pattern.sql from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\databricks\gold\01_scd2_merge_pattern.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\databricks\gold\01_scd2_merge_pattern.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\databricks\gold\01_scd2_merge_pattern.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\databricks\gold\01_scd2_merge_pattern.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/databricks/gold/01_scd2_merge_pattern.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/databricks/gold`.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/databricks/gold/01_scd2_merge_pattern.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\databricks\gold\01_scd2_merge_pattern.sql"` and require `True`.
4. Run `git status --short -- "sql/databricks/gold/01_scd2_merge_pattern.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/databricks/gold/01_scd2_merge_pattern.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/databricks/gold/01_scd2_merge_pattern.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 11.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: Databricks SQL / Spark SQL
-- Near-complete SCD2 pattern. Test on a copy before adapting it.
MERGE INTO IDENTIFIER(:target_dimension) AS target
USING IDENTIFIER(:changed_source_rows) AS source
ON target.business_key = source.business_key AND target.is_current = true
WHEN MATCHED AND target.record_hash <> source.record_hash THEN UPDATE SET
    target.is_current = false,
    target.effective_end_date = date_sub(current_date(), 1);

-- A second INSERT step adds new and changed current versions. The two-step reason is explained in Phase 11.
```

Line-by-line explanation

- **Line 1:** `-- Dialect: Databricks SQL / Spark SQL` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `-- Near-complete SCD2 pattern. Test on a copy before adapting it.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 3:** `MERGE INTO IDENTIFIER(:target_dimension) AS target` — `MERGE` compares source and target rows to update or insert deliberately; `INTO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `IDENTIFIER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(:)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target_dimension` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `USING IDENTIFIER(:changed_source_rows) AS source` — `USING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `IDENTIFIER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(:)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `changed_source_rows` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `ON target.business_key = source.business_key AND target.is_current = true` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AND` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.is_current` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `true` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `WHEN MATCHED AND target.record_hash <> source.record_hash THEN UPDATE SET` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MATCHED` is a

name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AND is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; target.record_hash is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; <> is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; source.record_hash is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; UPDATE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SET is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** target.is_current = false, — target.is_current is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; false is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** target.effective_end_date = date_sub(current_date(), 1); — target.effective_end_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; date_sub is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; current_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (), is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** blank line used only to separate logical sections for readability.
- **Line 10:** -- A second INSERT step adds new and changed current versions. The two-step reason is explained in Phase 11. is a comment for a human reader; it normally does not change data or execute business logic.

[Back to the Phase 11 lesson index](#)

What your screen should look like now

- Every Phase 11 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 11.3 completion checklist

databricks/notebooks/08_gold_dimensions.py was created by me, saved, located correctly, and inspected — [STATUS]

sql/databricks/gold/01_scd2_merge_pattern.sql was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 11.4](#) and recheck the root and branch.

Lesson 11.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Gold dimension 1 — `gold.dim_date`

Grain: One row per version of the date business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `date_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `date_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D1 — Build and validate `gold.dim_date`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_date`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_date` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_date` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.

7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 11 lesson index](#)

Teaching merge pattern

```
-- Teaching pattern; adapt the mapped columns for dim_date.  
MERGE INTO gold.dim_date AS target  
USING staged_dim_date AS source  
ON target.date_business_key = source.date_business_key  
  
WHEN MATCHED THEN UPDATE SET  
    target.updated_at = current_timestamp()  
WHEN NOT MATCHED THEN INSERT *;
```

Line-by-line explanation

- **Line 1:** `-- Teaching pattern; adapt the mapped columns for dim_date.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `MERGE INTO gold.dim_date AS target` — `MERGE` compares source and target rows to update or insert deliberately; `INTO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gold.dim_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `USING staged_dim_date AS source` — `USING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `staged_dim_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

tifier, or literal whose project-specific role is described in the surrounding explanation; source is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 4:** `ON target.date_business_key = source.date_business_key` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.date_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.date_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** blank line used only to separate logical sections for readability.
- **Line 6:** `WHEN MATCHED THEN UPDATE SET` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `UPDATE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SET` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `target.updated_at = current_timestamp()` — `target.updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `WHEN NOT MATCHED THEN INSERT *;` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INSERT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_date` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 2 — `gold.dim_customer`

Grain: One row per version of the customer business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `customer_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `customer_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: SCD Type 2 for history-bearing attributes.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D2 — Build and validate `gold.dim_customer`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_customer`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_customer` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply SCD Type 2 for history-bearing attributes.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_customer` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply SCD Type 2 for history-bearing attributes.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Teaching merge pattern

```
-- Teaching pattern; adapt the mapped columns for dim_customer.  
MERGE INTO gold.dim_customer AS target  
USING staged_dim_customer AS source  
ON target.customer_business_key = source.customer_business_key  
AND target.is_current = TRUE  
WHEN MATCHED THEN UPDATE SET  
    target.updated_at = current_timestamp()  
WHEN NOT MATCHED THEN INSERT *;
```

Line-by-line explanation

- **Line 1:** `-- Teaching pattern; adapt the mapped columns for dim_customer.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `MERGE INTO gold.dim_customer AS target` — `MERGE` compares source and target rows to update or insert deliberately; `INTO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gold.dim_customer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `USING staged_dim_customer AS source` — `USING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `staged_dim_customer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `ON target.customer_business_key = source.customer_business_key` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.customer_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.customer_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `AND target.is_current = TRUE` — `AND` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.is_current` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TRUE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `WHEN MATCHED THEN UPDATE SET` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `UPDATE` is a name, keyword, argu-

ment, identifier, or literal whose project-specific role is described in the surrounding explanation; SET is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** `target.updated_at = current_timestamp()` — `target.updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `WHEN NOT MATCHED THEN INSERT *;` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INSERT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Detailed SCD Type 2 timeline test

1. Select one fictional business key and record its original descriptive attributes.
2. Run the initial dimension load and record surrogate key, `effective_from`, `effective_to`, and `is_current`.
3. Change one history-tracked source attribute in a controlled later batch.
4. Run the merge.
5. Confirm the old row is closed immediately before the new row begins according to the documented boundary convention.
6. Confirm exactly one row is current.
7. Confirm a fact dated before the change resolves to the old surrogate key and a fact dated after the change resolves to the new key.
8. Rerun the changed batch and confirm no third row appears.

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_customer` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 3 — `gold.dim_product`

Grain: One row per version of the product business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `product_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `product_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: SCD Type 2 for history-bearing attributes.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D3 — Build and validate `gold.dim_product`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_product`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_product` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply SCD Type 2 for history-bearing attributes.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

Detailed SCD Type 2 timeline test

1. Select one fictional business key and record its original descriptive attributes.
2. Run the initial dimension load and record surrogate key, `effective_from`, `effective_to`, and `is_current`.
3. Change one history-tracked source attribute in a controlled later batch.
4. Run the merge.
5. Confirm the old row is closed immediately before the new row begins according to the documented boundary convention.
6. Confirm exactly one row is current.
7. Confirm a fact dated before the change resolves to the old surrogate key and a fact dated after the change resolves to the new key.
8. Rerun the changed batch and confirm no third row appears.

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_product` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 4 — `gold.dim_store`

Grain: One row per version of the store business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `store_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `store_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D4 — Build and validate `gold.dim_store`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_store`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_store` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.

Teaching merge pattern

```
-- Teaching pattern; adapt the mapped columns for dim_store.  
MERGE INTO gold.dim_store AS target  
USING staged_dim_store AS source  
ON target.store_business_key = source.store_business_key  
  
WHEN MATCHED THEN UPDATE SET  
    target.updated_at = current_timestamp()  
WHEN NOT MATCHED THEN INSERT *;
```

Line-by-line explanation

- **Line 1:** `-- Teaching pattern; adapt the mapped columns for dim_store.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `MERGE INTO gold.dim_store AS target` — `MERGE` compares source and target rows to update or insert deliberately; `INTO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gold.dim_store` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `USING staged_dim_store AS source` — `USING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `staged_dim_store` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `ON target.store_business_key = source.store_business_key` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.store_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.store_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** blank line used only to separate logical sections for readability.
- **Line 6:** `WHEN MATCHED THEN UPDATE SET` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `UPDATE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SET` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** `target.updated_at = current_timestamp()` — `target.updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `WHEN NOT MATCHED THEN INSERT *;` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INSERT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_store` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 5 — `gold.dim_employee`

Grain: One row per version of the `employee` business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `employee_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `employee_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D5 — Build and validate `gold.dim_employee`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_employee`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open databricks/notebooks/08_gold_dimensions.py.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for dim_employee in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/08_gold_dimensions.py.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for dim_employee in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location

with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Teaching merge pattern

```
-- Teaching pattern; adapt the mapped columns for dim_employee.  
MERGE INTO gold.dim_employee AS target  
USING staged_dim_employee AS source  
ON target.employee_business_key = source.employee_business_key  
  
WHEN MATCHED THEN UPDATE SET  
    target.updated_at = current_timestamp()  
WHEN NOT MATCHED THEN INSERT *;
```

Line-by-line explanation

- **Line 1:** `-- Teaching pattern; adapt the mapped columns for dim_employee.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `MERGE INTO gold.dim_employee AS target` — `MERGE` compares source and target rows to update or insert deliberately; `INTO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gold.dim_employee` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `USING staged_dim_employee AS source` — `USING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `staged_dim_employee` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `ON target.employee_business_key = source.employee_business_key` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.employee_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.employee_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** blank line used only to separate logical sections for readability.
- **Line 6:** `WHEN MATCHED THEN UPDATE SET` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `UPDATE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SET` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `target.updated_at = current_timestamp()` — `target.updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `WHEN NOT MATCHED THEN INSERT *` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INSERT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation queries and gates

- Surrogate key uniqueness.

- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_employee` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 6 — `gold.dim_supplier`

Grain: One row per version of the supplier business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `supplier_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `supplier_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D6 — Build and validate `gold.dim_supplier`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_supplier` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 7 — `gold.dim_promotion`

Grain: One row per version of the promotion business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `promotion_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `promotion_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D7 — Build and validate `gold.dim_promotion`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_promotion`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_promotion` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_promotion` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.

5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Teaching merge pattern

```
-- Teaching pattern; adapt the mapped columns for dim_promotion.
MERGE INTO gold.dim_promotion AS target
USING staged_dim_promotion AS source
ON target.promotion_business_key = source.promotion_business_key

WHEN MATCHED THEN UPDATE SET
    target.updated_at = current_timestamp()
WHEN NOT MATCHED THEN INSERT *;
```

Line-by-line explanation

- **Line 1:** -- Teaching pattern; adapt the mapped columns for dim_promotion. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** MERGE INTO gold.dim_promotion AS target — MERGE compares source and target rows to update or insert deliberately; INTO is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; gold.dim_promotion is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; target is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** USING staged_dim_promotion AS source — USING is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; staged_dim_promotion is a name, keyword, argu-

ment, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; source is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 4:** `ON target.promotion_business_key = source.promotion_business_key` — ON is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.promotion_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.promotion_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** blank line used only to separate logical sections for readability.
- **Line 6:** `WHEN MATCHED THEN UPDATE SET` — WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; MATCHED is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; UPDATE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SET is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `target.updated_at = current_timestamp()` — `target.updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `WHEN NOT MATCHED THEN INSERT *;` — WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; MATCHED is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; INSERT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_promotion` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 8 — `gold.dim_channel`

Grain: One row per version of the `channel` business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `channel_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `channel_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D8 — Build and validate gold.dim_channel

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate gold.dim_channel. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open databricks/notebooks/08_gold_dimensions.py.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for dim_channel in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/08_gold_dimensions.py.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for dim_channel in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Teaching merge pattern

```
-- Teaching pattern; adapt the mapped columns for dim_channel.
MERGE INTO gold.dim_channel AS target
  USING staged_dim_channel AS source
  ON target.channel_business_key = source.channel_business_key

WHEN MATCHED THEN UPDATE SET
  target.updated_at = current_timestamp()
WHEN NOT MATCHED THEN INSERT *;
```

Line-by-line explanation

- **Line 1:** `-- Teaching pattern; adapt the mapped columns for dim_channel.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `MERGE INTO gold.dim_channel AS target` — `MERGE` compares source and target rows to update or insert deliberately; `INTO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gold.dim_channel` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `USING staged_dim_channel AS source` — `USING` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `staged_dim_channel` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `ON target.channel_business_key = source.channel_business_key` — `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `target.channel_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `source.channel_business_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** blank line used only to separate logical sections for readability.
- **Line 6:** `WHEN MATCHED THEN UPDATE SET` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MATCHED` is a name, keyword, argument, identifier, or literal

whose project-specific role is described in the surrounding explanation; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; UPDATE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SET is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** `target.updated_at = current_timestamp()` — `target.updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `current_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `WHEN NOT MATCHED THEN INSERT *;` — `WHEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `MATCHED` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `THEN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `INSERT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_channel` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

Gold dimension 9 — `gold.dim_campaign`

Grain: One row per version of the campaign business entity when history is preserved; otherwise one current row per business key.

Natural/business key: `campaign_business_key` or the exact mapped source key documented for the dimension.

Surrogate key: `campaign_key`, generated independently of source identifiers.

Unknown-member strategy: Key 0 with readable values so facts with late, missing, or invalid references remain countable and monitorable.

Change behavior: Type 1 or deterministic rebuild behavior as documented for this dimension.

Source columns: The conformed Silver fields listed in the source-to-target mapping; do not pull raw Bronze values into Gold.

Dimension lookup use: Facts resolve the natural key plus event/effective date to the correct surrogate key.

Action 11.4.D9 — Build and validate `gold.dim_campaign`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and validate `gold.dim_campaign`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_campaign` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open `databricks/notebooks/08_gold_dimensions.py`.
2. LOOK FOR: Confirm the current batch's required Silver inputs exist and passed quality gates.
3. TYPE THIS: Declare the dimension grain and natural/business key for `dim_campaign` in a Markdown comment before code.
4. TYPE THIS: Create or verify the unknown member with surrogate key 0 and readable Unknown attributes.
5. TYPE THIS: Build the staged source with one deterministic row per business key.
6. PRESS: Run the initial-load section and inspect keys and counts.
7. TYPE THIS: Apply Type 1 or deterministic rebuild behavior as documented for this dimension.
8. PRESS: Run a controlled changed-record example.
9. LOOK FOR: Verify current-row uniqueness, effective dates when used, and no overlapping SCD2 windows.
10. PRESS: Rerun the same batch.
11. DO NOT CONTINUE UNTIL: The rerun creates no unintended duplicate and a sample fact lookup returns the expected surrogate key.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Validation queries and gates

- Surrogate key uniqueness.
- Business-key/current-row uniqueness.
- Unknown key 0 exists exactly once.
- Required descriptive attributes are not null for known rows.
- SCD2 effective windows do not overlap and exactly one current row exists per active business key.
- Initial-load count reconciles to the Silver survivor count plus the unknown row.
- Same-batch rerun is idempotent.
- A sample lookup before/after a Type 2 change resolves to the expected key.

Interview-ready explanation

"I built `dim_campaign` with a source-independent surrogate key, an explicit unknown member, deterministic change handling, and validation for key uniqueness and effective-date integrity. Facts use the dimension key that was valid at their event date."

What your screen should look like now

- The new Phase 11 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 11.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 11.5](#).

Lesson 11.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 11 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Type 1 versus Type 2 dimensions

Question:

Which changes need history?

Options considered:

- Type 1 overwrite all attributes.
- Type 2 all attributes.
- Selective Type 1/Type 2.

Beginner path selected:

Use Type 2 for customer and product history; simpler dimensions use Type 1 where appropriate.

Why this path was selected:

It demonstrates effective dating where historical context changes metric interpretation without adding unnecessary history everywhere.

Tradeoff:

SCD2 logic is more complex and creates multiple rows per business key.

What a company might do instead:

Companies define attribute-level change policies, late-arriving logic, audit metadata, and performance strategies.

How to explain this in an interview:

I selected SCD behavior by business meaning: customer/product changes preserve history, while corrective reference attributes can overwrite.

If you see Result A

Unknown members exist, current-row uniqueness holds, and an SCD2 change creates one valid new version. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

Overlapping dates, duplicate current rows, unstable keys, or an unexpired old version appear. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Databricks notebooks, Catalog Explorer, and SQL/Python cells.

Window/panel: Show unknown member, SCD2 timeline, current-row uniqueness, and sample surrogate-key lookup.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase11_build-gold-dimensions-surrogate-keys-and-scd-behavior_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 11's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 11 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 11.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.
- `MM` means a staged version exists and the file has additional unstaged edits.
- `A` means staged as a new file.
- `D` means deletion; stop and investigate unless deletion is deliberate.
- `R` means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 11.5.G4 — Inspect the unstaged diff for databricks/notebooks/08_gold_dimensions.py

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "databricks/notebooks/08_gold_dimensions.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "databricks/notebooks/08_gold_dimensions.py"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/notebooks/08_gold_dimensions.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.5.G5 — Stage only the reviewed file databricks/notebooks/08_gold_dimensions.py

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "databricks/notebooks/08_gold_dimensions.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "databricks/notebooks/08_gold_dimensions.py"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/notebooks/08_gold_dimensions.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 11.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.5.G7 — Create the Phase 11 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: build conformed gold dimensions"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: build conformed gold dimensions"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: build conformed gold dimensions"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Action 11.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 11 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: build conformed gold dimensions and the intended changed paths`.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 11.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.

7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 11 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 11 created the verified boundary described by **Build Gold dimensions, surrogate keys, and SCD behavior**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

Mini quiz

1. Multiple choice: Why does Phase 11 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 11.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 12 resolves dimension keys while building facts at declared grains.

Phase 11 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 12 — Build Gold fact tables and reconciled business measures

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Gold dimensions and facts with reconciled totals.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 13 converts correctness expectations into executable blocking tests.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 12 lesson index

1. Lesson 12.1 — Understand the phase and starting screen
2. Lesson 12.2 — Perform the notebook-guided actions one at a time
3. Lesson 12.3 — Create and understand the phase files
4. Lesson 12.4 — Build and validate required objects
5. Lesson 12.5 — Verify, troubleshoot, commit, teach back, and stop safely

Lesson 12.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Databricks notebooks, Catalog Explorer, and SQL/Python cells.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 12 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 11 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 12 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Databricks notebooks, Catalog Explorer, and SQL/Python cells. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 12 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 12 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 12 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 12.1 completion checklist

☐

I read why Phase 12 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 12.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 12 lesson index](#)

Lesson 12.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 12 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

Six facts at explicit grain: sales, returns, inventory snapshot, shipments, web sessions, and marketing spend. Each resolves dimension keys—including event-time SCD2—derives measures, prevents duplicate grain, handles unknown keys, reconciles to Silver, and optionally produces justified daily/monthly aggregates.

2. Why it matters

Facts are where double-counting becomes expensive. Grain determines keys, joins, and measure additivity. Resolving dimensions by natural key and event date preserves history; unknown handling and reconciliation keep incomplete context visible without dropping business events.

3. Words to know

Term	Plain-language definition
Transaction fact	One row per event, such as order item or return.
Periodic snapshot	One row per entity combination at a time point, such as daily stock.
Factless fact	Relationship/event fact with counts but few numeric measures.
Dimension lookup	Map a natural key/event date to a surrogate key.
Unknown-key rate	Share of facts using key 0.
Additive	Safe to sum across relevant dimensions.
Semi-additive	Safe across some dimensions but not time, such as inventory snapshot.
Non-additive	Ratio/percentage recalculated from components.
Degenerate dimension	Business identifier stored in fact, such as order_number.
Currency grain	Currency context that must be consistent/conversion-aware.
Event date / load date	When business event happened versus when platform processed it.
Aggregate table	Pre-summarized table used only when workload justifies it.
Duplicate prevention	Unique business grain and same-batch merge/replace.

4. What must already be completed

Gold dimensions pass all tests; Silver facts carry stable natural keys and valid measures; unknown rows exist. You can state each fact grain before coding.

5. Applications to open

Application	How to open it	Why it is open
Databricks notebook 09	Workspace.	Build fact_sales pattern and user-owned remaining facts.
Databricks SQL editor	Gold/Silver schemas.	Run grain/reconciliation/unknown checks.
VS Code	Open data dictionary, mapping, reference appendix after attempt.	Complete fact TODOs.
Architecture/star diagram	Open Gold star schema.	Trace relationships.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
SELECT order_item_id, COUNT(*) AS duplicate_count	Checks declared sales grain uniqueness.	Duplicate lines inflate every sales KPI.
WITH s AS (	Reconciles sales revenue Silver to Gold.	Dimension enrichment must not add/drop/multiply measures.
SELECT	Measures unresolved dimension context.	Key 0 is allowed but must be visible and thresholded.
SELECT snapshot_date_key, SUM(quantity_on_hand) AS on_hand	Shows stock per snapshot date.	Demonstrates correct time grain rather than summing all dates.
SELECT COUNT(*) AS delivered, SUM(CASE WHEN on_time_flag THEN 1 ELSE 0 END) AS on_time,	Validates shipment-level on-time numerator/denominator.	Prevents using order or line grain.

Fact relationship table

Fact	Grain	Core dimensions	Additive measures	Caution
fact_sales	valid order item	date, customer, product, store, employee, promotion, channel	quantity, sales, discount, cost, profit	orders are distinct, margin is ratio
fact_returns	return event/line	return date, customer, product, store	return quantity, refund	date-role compatibility
fact_inventory_snapshot	date-store-product	date, store, product	quantity/value across store/product	not across time
fact_shipments	shipment	ship/promised/delivery dates, customer, store	shipment count/cost	on-time is ratio
fact_web_sessions	session	date, customer, campaign, channel	session/event counts/duration	anonymous customer 0 legitimate
fact_marketing_spend	date-campaign-channel	date, campaign, channel	spend, impressions, clicks	currency/attribution

Ownership boundary

The workbook contains a complete teaching pattern for fact_sales and explicit TODOs for the remaining facts. You should implement them after the toy exercise, use three hint levels, and only then inspect the optional reference-answer section later in this workbook. This makes the project yours while keeping acceptance tests unambiguous.

MY TASK

Complete all five remaining fact transformations, replace unsafe ID shortcuts with natural-key/event-date lookups, add unique-grain and reconciliation tests, and justify whether any aggregate table is necessary.

STARTER SKELETON

```
# Example skeleton: fact_returns
returns = spark.table(f"{catalog}.{silver_schema}.returns").filter(F.col("batch_id") == batch_id)
# TODO(USER): join Silver sales/order context for store_code and purchase details.
# TODO(USER): lookup dim_customer/dim_product versions using natural key + return/purchase date policy.
# TODO(USER): map unresolved references to key 0 and retain return_id/order_item_id.
fact_returns = returns.select(
    (F.abs(F.xxhash64("return_id")) + 1).alias("return_key"),
    "return_id",
    # TODO(USER): remaining keys/measures/audit columns
)
# TODO(USER): assert unique return_id and reconcile quantity/refund to Silver.
```

Acceptance criteria: All six facts exist at documented unique grain, use correct dimension/date lookups, reconcile measures/rows under documented exclusions, track unknown rates, and remain stable on same-batch rerun.

HINT 1 — CONCEPT

Write one sentence grain, choose immutable business identifier, then list dimensions/measures before code.

HINT 2 — PSEUDOCODE

Pseudocode: Silver fact → natural key lookup → effective-date lookup → coalesce key 0 → derive measures → unique/reconcile tests.

HINT 3 — NEAR-COMPLETE PATTERN

Follow fact_sales structure, but adapt date roles and semi-additive behavior; open reference only after a failed attempt.

13. Expected files or output

- 6 Gold fact Delta tables.
- Grain/relationship matrix.
- Unknown-key monitoring.
- Silver-to-Gold count/amount reconciliations.
- Same-batch stable counts.
- Aggregate decision record.

14. How to verify

- Unique business grain per fact.
- No orphan surrogate keys.
- Sales arithmetic identity.
- Inventory selected-date behavior.
- Shipment sample on-time logic.
- Web conversion links do not duplicate order attribution unexpectedly.
- Spend USD/ranges valid.

15. Automated tests

- Unique-key and not-null tests.
- Dimension RI and unknown-rate thresholds.
- Date/numeric ranges.
- Silver-to-Gold row/amount reconciliation.
- Event-time SCD lookup test using controlled history.
- Same-batch rerun.
- Additivity tests/semantic cautions.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
All facts use unknown key	Natural key missing/case mismatch or date join wrong.	Anti-join Silver keys to dimension; inspect date ranges.	Carry standardized natural keys; join on key + event date; use 0 only unresolved.	Unknown rate expected.
Fact count exceeds Silver	Many-to-many dimension join/overlap.	Compare count after each join; dimension uniqueness/overlap tests.	Fix dimension SCD state or lookup condition.	Count reconciles.
Revenue differs	Rows lost/duplicated or formula/type/rounding changed.	Reconcile row/quantity/gross/discount/net stepwise.	Fix first divergent boundary; preserve decimal types.	Difference tolerance met.
Inventory total enormous	Summed multiple snapshots.	Group by snapshot date.	Filter latest/selected date; label semi-additive.	One-date validation matches source.
Fact rerun duplicates	Append without stable batch/grain delete/merge.	Group grain by batch/count.	Replace same batch or MERGE unique identifier.	Stable.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why is inventory semi-additive?
2. Why does a fact keep order_number even though it is not a dimension table?
3. How should an anonymous web session map customer?
4. Why is event-time SCD lookup necessary?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What is the grain of fact_marketing_spend?
2. Which measure should not be summed across inventory dates?
3. What does a high unknown-product rate tell you?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture the star schema, six fact counts/grains, one SCD event-time lookup, revenue reconciliation, and same-batch duplicate test.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: build and reconcile gold fact tables
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

- ☐ All six grains declared — [STATUS]
- ☐ fact_sales verified — [STATUS]
- ☐ returns/inventory/shipments completed — [STATUS]
- ☐ web/spend completed — [STATUS]
- ☐ SCD lookups verified — [STATUS]
- ☐ Unknown rates acceptable — [STATUS]
- ☐ Reconciliations pass — [STATUS]
- ☐ Rerun stable — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-12. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-12.

Next phase: Phase 13 expands the tests into a stored, blocking publication quality gate.

Required action cards

Action 12.2.1 — Write the six grain statements before opening final code: sales one valid order item; returns one return event

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Write the six grain statements before opening final code: sales one valid order item; returns one return event. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Write the six grain statements before opening final code: sales one valid order item; returns one return event/line; inventory one snapshot date-store-product; shipments one shipment; web sessions one session; spend one date-campaign-channel.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Write the six grain statements before opening final code: sales one valid order item; returns one return event/line; inventory one snapshot date-store-product; shipments one shipment; web sessions one session; spend one date-campaign-channel.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 12 lesson index](#)

Action 12.2.2 — Use a toy movie-ticket example to practice dimension lookup: a theater name change produces two versions; a ti

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Use a toy movie-ticket example to practice dimension lookup: a theater name change produces two versions; a ti. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Use a toy movie-ticket example to practice dimension lookup: a theater name change produces two versions; a ticket joins the version valid on show date.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

Use a toy movie-ticket example to practice dimension lookup: a theater name change produces two versions; a ticket joins the version valid on show date.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 12 lesson index](#)

Action 12.2.3 — Open 09_gold_facts. Replace any ID regex shortcut with joins from Silver natural keys. For customer/product

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Open 09_gold_facts. Replace any ID regex shortcut with joins from Silver natural keys. For customer/product . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open 09_gold_facts. Replace any ID regex shortcut with joins from Silver natural keys. For customer/product SCD2, include event_date BETWEEN effective_start_date AND effective_end_date.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 3****Action**

Open 09_gold_facts. Replace any ID regex shortcut with joins from Silver natural keys. For customer/product SCD2, include event_date BETWEEN effective_start_date AND effective_end_date.

Before continuing☐

Action 12.2.10 — For every fact, enforce unique grain, required dimension keys/not-null, unknown threshold, range, and Silver r

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

For every fact, enforce unique grain, required dimension keys/not-null, unknown threshold, range, and Silver r. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: For every fact, enforce unique grain, required dimension keys/not-null, unknown threshold, range, and Silver reconciliation.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 10****Action**

For every fact, enforce unique grain, required dimension keys/not-null, unknown threshold, range, and Silver reconciliation.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 12 lesson index](#)

Action 12.2.11 — Create daily/monthly sales aggregate only after querying demonstrates need; document exact grain and component

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Create daily/monthly sales aggregate only after querying demonstrates need; document exact grain and component. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Create daily/monthly sales aggregate only after querying demonstrates need; document exact grain and components. Ratios should not be stored as sums unless semantics are safe.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 11

Action

Create daily/monthly sales aggregate only after querying demonstrates need; document exact grain and components. Ratios should not be stored as sums unless semantics are safe.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 12 lesson index](#)

Action 12.2.12 — Rerun same batch and prove no duplicate fact grain.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Rerun same batch and prove no duplicate fact grain. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Rerun same batch and prove no duplicate fact grain.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 12****Action**

Rerun same batch and prove no duplicate fact grain.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 12 lesson index](#)

Action 12.2.C1 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT order_item_id, COUNT(*) AS duplicate_count
FROM northstar_retail.gold.fact_sales
GROUP BY order_item_id
HAVING COUNT(*) > 1;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT order_item_id, COUNT(*) AS duplicate_count` — `SELECT` requests data without changing it unless combined with a modifying statement; `order_item_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `duplicate_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 2:** FROM northstar_retail.gold.fact_sales — FROM identifies the source table or query; northstar_retail.gold.fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** GROUP BY order_item_id — GROUP is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; BY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; order_item_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** HAVING COUNT(*) > 1; — HAVING is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; > is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.2.C2 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
WITH s AS (
  SELECT SUM(net_sales_amount) AS amount FROM northstar_retail.silver.sales WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ'
), g AS (
  SELECT SUM(net_sales_amount) AS amount FROM northstar_retail.gold.fact_sales WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ'
)
SELECT s.amount AS silver_amount, g.amount AS gold_amount, g.amount-s.amount AS difference FROM s CROSS JOIN g;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** WITH s AS (— WITH is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; s is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SELECT SUM(net_sales_amount) AS amount FROM northstar_retail.silver.sales WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ' — SELECT requests data without changing it unless combined with a modifying statement; SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; net_sales_amount is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; amount is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FROM identifies the source table or query; northstar_retail.silver.sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHERE filters rows to those meeting a condition; batch_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

- **Line 3:** `) , g AS ( — )`, is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `g` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `SELECT SUM(net_sales_amount) AS amount FROM northstar_retail.gold.fact_sales WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ' — SELECT` requests data without changing it unless combined with a modifying statement; `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `net_sales_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `northstar_retail.gold.fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `WHERE` filters rows to those meeting a condition; `batch_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 5:** `) — )` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `SELECT s.amount AS silver_amount, g.amount AS gold_amount, g.amount-s.amount AS difference FROM s CROSS JOIN g; — SELECT` requests data without changing it unless combined with a modifying statement; `s.amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `silver_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `g.amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gold_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `g.amount-s.amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `difference` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.2.C3 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT
  COUNT(*) AS rows,
  SUM(CASE WHEN customer_key=0 THEN 1 ELSE 0 END) AS unknown_customer,
  SUM(CASE WHEN product_key=0 THEN 1 ELSE 0 END) AS unknown_product,
  SUM(CASE WHEN store_key=0 THEN 1 ELSE 0 END) AS unknown_store
FROM northstar_retail.gold.fact_sales
WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ';
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT — SELECT requests data without changing it unless combined with a modifying statement
- **Line 2:** COUNT(*) AS rows, — COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; rows is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** SUM(CASE WHEN customer_key=0 THEN 1 ELSE 0 END) AS unknown_customer, — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CASE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; customer_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression; ELSE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; END is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 4:** SUM(CASE WHEN product_key=0 THEN 1 ELSE 0 END) AS unknown_product, — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CASE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; product_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression; ELSE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; END is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 5:** SUM(CASE WHEN store_key=0 THEN 1 ELSE 0 END) AS unknown_store — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CASE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; store_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression; ELSE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; END is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 6:** FROM northstar_retail.gold.fact_sales — FROM identifies the source table or query; northstar_retail.gold.fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ'; — WHERE filters rows to those meeting a condition; batch_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 'EXT-YYYYMMDDTHHMMSSZ' is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.2.C4 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT snapshot_date_key, SUM(quantity_on_hand) AS on_hand
FROM northstar_retail.gold.fact_inventory_snapshot
GROUP BY snapshot_date_key
ORDER BY snapshot_date_key;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT snapshot_date_key, SUM(quantity_on_hand) AS on_hand — SELECT requests data without changing it unless combined with a modifying statement; snapshot_date_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; quantity_on_hand is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; on_hand is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** FROM northstar_retail.gold.fact_inventory_snapshot — FROM identifies the source table or query; northstar_retail.gold.fact_inventory_snapshot is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** GROUP BY snapshot_date_key — GROUP is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; BY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; snapshot_date_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** ORDER BY snapshot_date_key; — ORDER is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; BY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; snapshot_date_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 12.2.C5 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT COUNT(*) AS delivered, SUM(CASE WHEN on_time_flag THEN 1 ELSE 0 END) AS on_time,  
      SUM(CASE WHEN on_time_flag THEN 1 ELSE 0 END) / NULLIF(COUNT(*),0) AS on_time_rate  
FROM northstar_retail.gold.fact_shipments  
WHERE delivery_date_key <> 0;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT COUNT(*) AS delivered, SUM(CASE WHEN on_time_flag THEN 1 ELSE 0 END) AS on_time, — SELECT requests data without changing it unless combined with a modifying statement; COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; delivered is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CASE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; on_time_flag is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 2:** SUM(CASE WHEN on_time_flag THEN 1 ELSE 0 END) / NULLIF(COUNT(*),0) AS on_time_rate — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CASE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; WHEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; on_time_flag is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; THEN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression; ELSE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; END is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; / is a path, relative location, branch-style name, or file argument; verify every character before running it; remaining punctuation and identifiers continue the same statement.
- **Line 3:** FROM northstar_retail.gold.fact_shipments — FROM identifies the source table or query; northstar_retail.gold.fact_shipments is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** WHERE delivery_date_key <> 0; — WHERE filters rows to those meeting a condition; delivery_date_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; <> is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 12.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 12 starting-screen checklist and re-verify the active context.

Lesson 12.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 12 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — databricks/

Exact folder name: databricks

Exact parent: repository root

Why it is needed now: Phase 12 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: databricks.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 12.D1.1 — Create the folder databricks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.

6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\databricks" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\databricks" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\databricks" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — `sql/`

Exact folder name: `sql`

Exact parent: `repository root`

Why it is needed now: Phase 12 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `repository root` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `sql`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 12.D2.1 — Create the folder `sql`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 12.D3.1 — Create the folder databricks/notebooks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks\notebooks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks\notebooks" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\notebooks"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\databricks\notebooks" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\databricks\notebooks" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\databricks\notebooks" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/databricks/

Exact folder name: databricks

Exact parent: sql

Why it is needed now: Phase 12 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path sql one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: databricks.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 12.D4.1 — Create the folder sql/databricks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql\databricks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\sql\databricks" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\sql\databricks" is a path,

relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\sql\databricks\gold" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\databricks\gold" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\databricks\gold" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — databricks/notebooks/09_gold_facts.py

Exact filename: `09_gold_facts.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `databricks/notebooks` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 12.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `databricks/notebooks` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `09_gold_facts.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `09_gold_facts.py` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 12.F1.1 — Create the file `databricks/notebooks/09_gold_facts.py` from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\databricks\notebooks\09_gold_facts.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\databricks\notebooks\09_gold_facts.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\notebooks\09_gold_facts.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\databricks\notebooks\09_gold_facts.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "databricks/notebooks/09_gold_facts.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `databricks/notebooks`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `databricks/notebooks/09_gold_facts.py`.
3. In PowerShell at the repository root, run `Test-Path ".\databricks\notebooks\09_gold_facts.py"` and require `True`.
4. Run `git status --short -- "databricks/notebooks/09_gold_facts.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for databricks/notebooks/09_gold_facts.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: databricks/notebooks/09_gold_facts.py

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 12.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Databricks notebook source
# Northstar Retail End-to-End Data Platform
# This file is a Git-friendly Databricks source notebook.
# Track A reads files that you manually uploaded to a Unity Catalog volume.
# It never attempts to reach SQL Server or PostgreSQL on localhost.

# COMMAND -----
# MAGIC %md
# MAGIC # 09 – Gold facts
# MAGIC Looks up effective dimension keys at the event date and builds facts at declared grain.

# COMMAND -----

[Back to the Phase 12 lesson index](#)

File introduction — `sql/databricks/gold/02_kpi_views.sql`

Exact filename: `02_kpi_views.sql`

Filename extension: `.sql`. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `sql/databricks/gold` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 12.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `sql/databricks/gold` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `02_kpi_views.sql`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `02_kpi_views.sql` and an empty file under the correct parent folder.

10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 12.F2.1 — Create the file `sql/databricks/gold/02_kpi_views.sql` from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\databricks\gold\02_kpi_views.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item` -ItemType File -Path ".\sql\databricks\gold\02_kpi_views.sql" -ErrorAction Stop — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\sql\databricks\gold\02_kpi_views.sql` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\databricks\gold\02_kpi_views.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/databricks/gold/02_kpi_views.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.

7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under sql/databricks/gold.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with sql/databricks/gold/02_kpi_views.sql.
3. In PowerShell at the repository root, run Test-Path ".\sql\databricks\gold\02_kpi_views.sql" and require True.
4. Run git status --short -- "sql/databricks/gold/02_kpi_views.sql" to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for sql/databricks/gold/02_kpi_views.sql

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: sql/databricks/gold/02_kpi_views.sql

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 12.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: Databricks SQL / Spark SQL
CREATE OR REPLACE VIEW IDENTIFIER(:catalog || '.gold_semantic.executive_daily_kpi') AS
SELECT
  d.full_date,
  SUM(f.net_sales_amount) AS total_revenue,
  SUM(f.gross_profit_amount) AS gross_profit,

specific role is described in the surrounding explanation; `d.full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

[Back to the Phase 12 lesson index](#)

What your screen should look like now

- Every Phase 12 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 12.3 completion checklist

☐

`databricks/notebooks/09_gold_facts.py` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`sql/databricks/gold/02_kpi_views.sql` was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with `Ctrl+S`. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 12.4](#) and recheck the root and branch.

Lesson 12.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Gold fact 1 — `gold.fact_sales`

Declared grain: one row per valid order item.

Dimension keys: date, customer, product, store, employee, promotion, channel. Each lookup must name its business key and effective-date rule.

Measures: `quantity`, `gross_sales_amount`, `discount_amount`, `net_sales_amount`, `cost_of_goods_sold`, `gross_profit_amount`.

Additivity: Monetary and quantity measures are generally additive across compatible dimensions; snapshot balances are not safely additive across snapshot dates; ratios and flags must be aggregated with documented denominators.

Unknown keys: Use key 0 rather than dropping the fact, then monitor the unknown-key rate.

Duplicate prevention: Define a stable business-event key at the declared grain and enforce same-batch idempotency.

Incremental rule: Process the named batch or watermark range and do not reprocess unrelated history unless the repair strategy says so.

Action 12.4.F1 — Build and reconcile `gold.fact_sales`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and reconcile gold.fact_sales. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per valid order item above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per valid order item above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 12 lesson index](#)

Teaching fact-build pattern

```
fact_source = spark.table("gold_stage.fact_sales")
deduped = fact_source.dropDuplicates(["_business_event_key"])
resolved = (deduped
    .withColumn("date_key", F.coalesce(F.col("date_key"), F.lit(0)))
    .withColumn("_batch_id", F.lit(batch_id)))
(resolved.write.format("delta")
    .mode("overwrite")
    .option("replaceWhere", f"_batch_id = '{batch_id}'")
    .saveAsTable("gold.fact_sales"))
```

Line-by-line explanation

- **Line 1:** `fact_source = spark.table("gold_stage.fact_sales")` — `fact_source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `spark.table` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"gold_stage.fact_sales"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 8:** `.option("replaceWhere", f"_batch_id = '{batch_id}'")` — `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `option` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"replaceWhere"` is a quoted literal; the quotation marks preserve spaces or mark text; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"_batch_id = '{batch_id}'"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** `.saveAsTable("gold.fact_sales")` — `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `saveAsTable` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"gold.fact_sales"` is a quoted literal; the quotation marks preserve spaces or mark text; `))` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Reconciliation worksheet

Check	Upstream value	Gold value	Difference	Pass condition	My verified result
Accepted event rows	[ENTER]	[ENTER]	[CALCULATE]	zero unless explicitly aggregated	[ENTER]
Primary quantity	[ENTER]	[ENTER]	[CALCULATE]	zero within declared logic	[ENTER]
Primary amount	[ENTER]	[ENTER]	[CALCULATE]	within rounding tolerance	[ENTER]
Unknown dimension keys	[ENTER]	[ENTER]	n/a	monitored and explained	[ENTER]
Duplicate business-event keys	n/a	[ENTER]	n/a	zero	[ENTER]
Same-batch rerun row growth	n/a	[ENTER]	n/a	zero unintended growth	[ENTER]

Sample business questions

1. What does one row mean, and which dimensions can filter it?
2. Which measures can be summed across dates, and which cannot?
3. Which source rows reconcile to one chosen fact row?
4. What happens when a dimension record arrives late?
5. What query proves that a rerun did not duplicate the business event?

Interview-ready explanation

"I built `fact_sales` at one row per valid order item, resolved conformed dimension keys with explicit unknown handling, derived documented measures, and reconciled both counts and amounts. A deterministic event key made incremental reruns testable."

Gold fact 2 — `gold.fact_returns`

Declared grain: one row per accepted returned product line.

Dimension keys: return date, customer, product, store, channel. Each lookup must name its business key and effective-date rule.

Measures: `return_quantity`, `refund_amount`.

Additivity: Monetary and quantity measures are generally additive across compatible dimensions; snapshot balances are not safely additive across snapshot dates; ratios and flags must be aggregated with documented denominators.

Unknown keys: Use key 0 rather than dropping the fact, then monitor the unknown-key rate.

Duplicate prevention: Define a stable business-event key at the declared grain and enforce same-batch idempotency.

Incremental rule: Process the named batch or watermark range and do not reprocess unrelated history unless the repair strategy says so.

Action 12.4.F2 — Build and reconcile `gold.fact_returns`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and reconcile `gold.fact_returns`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/09_gold_facts.py`.
2. TYPE THIS: Write the grain `one row per accepted returned product line` above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select `one row per business event` at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per accepted returned product line above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Reconciliation worksheet

Check	Upstream value	Gold value	Difference	Pass condition	My verified result
Accepted event rows	[ENTER]	[ENTER]	[CALCULATE]	zero unless explicitly aggregated	[ENTER]
Primary quantity	[ENTER]	[ENTER]	[CALCULATE]	zero within declared logic	[ENTER]
Primary amount	[ENTER]	[ENTER]	[CALCULATE]	within rounding tolerance	[ENTER]
Unknown dimension keys	[ENTER]	[ENTER]	n/a	monitored and explained	[ENTER]
Duplicate business-event keys	n/a	[ENTER]	n/a	zero	[ENTER]
Same-batch rerun row growth	n/a	[ENTER]	n/a	zero unintended growth	[ENTER]

Sample business questions

1. What does one row mean, and which dimensions can filter it?
2. Which measures can be summed across dates, and which cannot?
3. Which source rows reconcile to one chosen fact row?
4. What happens when a dimension record arrives late?
5. What query proves that a rerun did not duplicate the business event?

Interview-ready explanation

"I built fact_returns at one row per accepted returned product line, resolved conformed dimension keys with explicit unknown handling, derived documented measures, and reconciled both counts and amounts. A deterministic event key made incremental reruns testable."

Gold fact 3 — gold.fact_inventory_snapshot

Declared grain: one row per product-store snapshot date.

Dimension keys: snapshot date, product, store. Each lookup must name its business key and effective-date rule.

Measures: quantity_on_hand, quantity_reserved, reorder_point, stockout_risk_flag.

Additivity: Monetary and quantity measures are generally additive across compatible dimensions; snapshot balances are not safely additive across snapshot dates; ratios and flags must be aggregated with documented denominators.

Unknown keys: Use key 0 rather than dropping the fact, then monitor the unknown-key rate.

Duplicate prevention: Define a stable business-event key at the declared grain and enforce same-batch idempotency.

Incremental rule: Process the named batch or watermark range and do not reprocess unrelated history unless the repair strategy says so.

Action 12.4.F3 — Build and reconcile gold.fact_inventory_snapshot

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and reconcile gold.fact_inventory_snapshot. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per product-store snapshot date above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per product-store snapshot date above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Sample business questions

1. What does one row mean, and which dimensions can filter it?
2. Which measures can be summed across dates, and which cannot?

3. Which source rows reconcile to one chosen fact row?
4. What happens when a dimension record arrives late?
5. What query proves that a rerun did not duplicate the business event?

Interview-ready explanation

"I built fact_inventory_snapshot at one row per product-store snapshot date, resolved conformed dimension keys with explicit unknown handling, derived documented measures, and reconciled both counts and amounts. A deterministic event key made incremental reruns testable."

Gold fact 4 — gold.fact_shipments

Declared grain: one row per shipment.

Dimension keys: ship date, delivery date, customer, store, channel. Each lookup must name its business key and effective-date rule.

Measures: shipping_cost, transit_days, on_time_flag.

Additivity: Monetary and quantity measures are generally additive across compatible dimensions; snapshot balances are not safely additive across snapshot dates; ratios and flags must be aggregated with documented denominators.

Unknown keys: Use key 0 rather than dropping the fact, then monitor the unknown-key rate.

Duplicate prevention: Define a stable business-event key at the declared grain and enforce same-batch idempotency.

Incremental rule: Process the named batch or watermark range and do not reprocess unrelated history unless the repair strategy says so.

Action 12.4.F4 — Build and reconcile gold.fact_shipments

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and reconcile gold.fact_shipments. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per shipment above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Reconciliation worksheet

Check	Upstream value	Gold value	Difference	Pass condition	My verified result
Accepted event rows	[ENTER]	[ENTER]	[CALCULATE]	zero unless explicitly aggregated	[ENTER]
Primary quantity	[ENTER]	[ENTER]	[CALCULATE]	zero within declared logic	[ENTER]
Primary amount	[ENTER]	[ENTER]	[CALCULATE]	within rounding tolerance	[ENTER]
Unknown dimension keys	[ENTER]	[ENTER]	n/a	monitored and explained	[ENTER]
Duplicate business-event keys	n/a	[ENTER]	n/a	zero	[ENTER]
Same-batch rerun row growth	n/a	[ENTER]	n/a	zero unintended growth	[ENTER]

Sample business questions

1. What does one row mean, and which dimensions can filter it?
2. Which measures can be summed across dates, and which cannot?
3. Which source rows reconcile to one chosen fact row?
4. What happens when a dimension record arrives late?
5. What query proves that a rerun did not duplicate the business event?

Interview-ready explanation

"I built fact_shipments at one row per shipment, resolved conformed dimension keys with explicit unknown handling, derived documented measures, and reconciled both counts and amounts. A deterministic event key made incremental reruns testable."

Gold fact 5 — gold.fact_web_sessions

Declared grain: one row per conformed web session or declared aggregate session grain.

Dimension keys: session date, customer/web user, campaign, channel. Each lookup must name its business key and effective-date rule.

Measures: session_count, converted_flag, converted_order_id.

Additivity: Monetary and quantity measures are generally additive across compatible dimensions; snapshot balances are not safely additive across snapshot dates; ratios and flags must be aggregated with documented denominators.

Unknown keys: Use key 0 rather than dropping the fact, then monitor the unknown-key rate.

Duplicate prevention: Define a stable business-event key at the declared grain and enforce same-batch idempotency.

Incremental rule: Process the named batch or watermark range and do not reprocess unrelated history unless the repair strategy says so.

Action 12.4.F5 — Build and reconcile gold.fact_web_sessions

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and reconcile gold.fact_web_sessions. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per conformed web session or declared aggregate session grain above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per conformed web session or declared aggregate session grain above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Sample business questions

1. What does one row mean, and which dimensions can filter it?
2. Which measures can be summed across dates, and which cannot?
3. Which source rows reconcile to one chosen fact row?
4. What happens when a dimension record arrives late?
5. What query proves that a rerun did not duplicate the business event?

Interview-ready explanation

"I built `fact_web_sessions` at one row per conformed web session or declared aggregate session grain, resolved conformed dimension keys with explicit unknown handling, derived documented measures, and reconciled both counts and amounts. A deterministic event key made incremental reruns testable."

Gold fact 6 — `gold.fact_marketing_spend`

Declared grain: one row per date-campaign-channel spend record.

Dimension keys: spend date, campaign, channel. Each lookup must name its business key and effective-date rule.

Measures: `spend_amount`, `impressions`, `clicks`.

Additivity: Monetary and quantity measures are generally additive across compatible dimensions; snapshot balances are not safely additive across snapshot dates; ratios and flags must be aggregated with documented denominators.

Unknown keys: Use key 0 rather than dropping the fact, then monitor the unknown-key rate.

Duplicate prevention: Define a stable business-event key at the declared grain and enforce same-batch idempotency.

Incremental rule: Process the named batch or watermark range and do not reprocess unrelated history unless the repair strategy says so.

Action 12.4.F6 — Build and reconcile `gold.fact_marketing_spend`

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Build and reconcile `gold.fact_marketing_spend`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open `databricks/notebooks/09_gold_facts.py`.
2. TYPE THIS: Write the grain one row per date-campaign-channel spend record above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.

10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open databricks/notebooks/09_gold_facts.py.
2. TYPE THIS: Write the grain one row per date-campaign-channel spend record above the fact-building section.
3. LOOK FOR: Confirm every required dimension is already verified.
4. TYPE THIS: Select one row per business event at the declared grain.
5. TYPE THIS: Resolve each dimension key by business key and event/effective date.
6. TYPE THIS: Map missing dimension references to unknown key 0 and increment a monitored exception count.
7. TYPE THIS: Derive measures only from documented source columns and formulas.
8. TYPE THIS: Add a deterministic duplicate-prevention key and current batch metadata.
9. PRESS: Run the batch-scoped write.
10. PRESS: Run source-to-fact count and amount reconciliation.
11. PRESS: Run the same batch again.
12. DO NOT CONTINUE UNTIL: Counts/totals reconcile, no unintended duplicate appears, and sample business questions return explainable results.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

- Line 6:** `(resolved.write.format("delta"))` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `resolved.write.format` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"delta"` is a quoted

literal; the quotation marks preserve spaces or mark text;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** `.mode("overwrite")` — . is a path, relative location, branch-style name, or file argument; verify every character before running it; mode is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "overwrite" is a quoted literal; the quotation marks preserve spaces or mark text;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `.option("replaceWhere", f"_batch_id = '{batch_id}')` — . is a path, relative location, branch-style name, or file argument; verify every character before running it; option is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "replaceWhere" is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; f is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "_batch_id = '{batch_id}'" is a quoted literal; the quotation marks preserve spaces or mark text;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** `.saveAsTable("gold.fact_marketing_spend")` — . is a path, relative location, branch-style name, or file argument; verify every character before running it; saveAsTable is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "gold.fact_marketing_spend" is a quoted literal; the quotation marks preserve spaces or mark text;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Reconciliation worksheet

Check	Upstream value	Gold value	Difference	Pass condition	My verified result
Accepted event rows	[ENTER]	[ENTER]	[CALCULATE]	zero unless explicitly aggregated	[ENTER]
Primary quantity	[ENTER]	[ENTER]	[CALCULATE]	zero within declared logic	[ENTER]
Primary amount	[ENTER]	[ENTER]	[CALCULATE]	within rounding tolerance	[ENTER]
Unknown dimension keys	[ENTER]	[ENTER]	n/a	monitored and explained	[ENTER]
Duplicate business-event keys	n/a	[ENTER]	n/a	zero	[ENTER]
Same-batch rerun row growth	n/a	[ENTER]	n/a	zero unintended growth	[ENTER]

Sample business questions

1. What does one row mean, and which dimensions can filter it?
2. Which measures can be summed across dates, and which cannot?
3. Which source rows reconcile to one chosen fact row?
4. What happens when a dimension record arrives late?
5. What query proves that a rerun did not duplicate the business event?

Interview-ready explanation

"I built fact_marketing_spend at one row per date-campaign-channel spend record, resolved conformed dimension keys with explicit unknown handling, derived documented measures, and reconciled both counts and amounts. A deterministic event key made incremental reruns testable."

What your screen should look like now

- The new Phase 12 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 12.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 12.5](#).

Lesson 12.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 12 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Verification before automation

Question:

Should the phase prioritize a visible manual verification or jump directly to automation?

Options considered:

- Manual verification first, then automation.
- Automation without a known-good baseline.
- Manual operation forever.

Beginner path selected:

Establish one verified manual baseline and then automate repeatable checks.

Why this path was selected:

A known-good example makes failures interpretable and prevents automation from hiding a wrong assumption.

Tradeoff:

The first run takes longer.

What a company might do instead:

Teams often pair infrastructure as code and automated tests with controlled bootstrap and acceptance procedures.

How to explain this in an interview:

I established a verified baseline, then encoded the same contract in tests and orchestration so automation preserved meaning rather than just speed.

If you see Result A

Each fact passes its declared grain, dimension lookup, unknown-key, and amount/count reconciliation. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

Duplicate grain, unresolved keys beyond policy, or mismatched measures appear. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Databricks notebooks, Catalog Explorer, and SQL/Python cells.

Window/panel: Show fact grain sample, dimension keys, measures, and count/amount reconciliation.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase12_build-gold-fact-tables-and-reconciled-business-measures_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 12's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 12 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 12.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.

- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 12.5.G4 — Inspect the unstaged diff for databricks/notebooks/09_gold_facts.py

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "databricks/notebooks/09_gold_facts.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "databricks/notebooks/09_gold_facts.py"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/notebooks/09_gold_facts.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.5.G5 — Stage only the reviewed file databricks/notebooks/09_gold_facts.py

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.

2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "databricks/notebooks/09_gold_facts.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "databricks/notebooks/09_gold_facts.py"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/notebooks/09_gold_facts.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 12.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.5.G7 — Create the Phase 12 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: build reconciled gold facts"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: build reconciled gold facts"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: build reconciled gold facts"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Action 12.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.

3. **CLICK:** Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. **TYPE THIS:** Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. **PRESS:** Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. **LOOK FOR:** Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. **DO NOT CONTINUE UNTIL:** Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 12 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message feat: build reconciled gold facts and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 12.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 12 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 12 created the verified boundary described by **Build Gold fact tables and reconciled business measures**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 12 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
4. What command would you use first to confirm the PowerShell current folder before a repository command?
5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?

6. Design choice: Explain one tradeoff of Track A and one production alternative.
7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
8. Ownership: Which status may you select only after personally performing and inspecting the verification?

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** PLANNED, CREATED BY USER, and RUN BY USER describe earlier states; only inspected evidence supports verification.

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.

- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 12.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 13 converts correctness expectations into executable blocking tests.

Phase 12 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 13 — Build data-quality, reconciliation, and failure gates

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Runnable transformations and quality gates.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 14 connects them in dependency order and proves repair behavior.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 13 lesson index

1. [Lesson 13.1 — Understand the phase and starting screen](#)
2. [Lesson 13.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 13.3 — Create and understand the phase files](#)
4. [Lesson 13.4 — Build and validate required objects](#)
5. [Lesson 13.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 13.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** VS Code tests, Databricks notebooks, Catalog Explorer, and Job task output.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 13 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 12 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 13 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

VS Code tests, Databricks notebooks, Catalog Explorer, and Job task output. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 13 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 13 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 13 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 13.1 completion checklist

☐

I read why Phase 13 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 13.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 13 lesson index](#)

Lesson 13.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 13 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A risk-based test suite across local Python, source SQL, Databricks Bronze/Silver/Gold, and SQL Server publication, with stored `quality.test_results`, clear required versus warning checks, schema/freshness/quarantine monitoring, and a demonstrated failed gate that blocks publication.

2. Why it matters

Data quality is not a single 'not null' query. Trust depends on boundary reconciliations, grain, arithmetic, SCD state, freshness, schema stability, quarantine visibility, and failure behavior. A gate has value only when downstream publication truly depends on it.

3. Words to know

Term	Plain-language definition
Assertion	Condition that fails execution when false.
Required check	Failure blocks publication.
Warning check	Visible concern that does not block under current policy.
Threshold	Allowed limit such as unknown-key share $\leq$ 5%.
Freshness	How recent the latest accepted event/snapshot is.
Schema drift	New/missing/changed source column/type.
Reconciliation	Independent comparison across layers.
Test result table	Stored batch/check/actual/expected/status evidence.
False positive/negative	Test fails good data or passes bad data.
Quality gate	Dependency task that stops downstream publication on required failure.
Observability	Logs/metrics/status making operation understandable.
Repair run	Rerun failed and dependent tasks after correction.
Tolerance	Documented acceptable numeric difference, commonly rounding-related.

4. What must already be completed

All required Gold dimensions/facts exist and local tests can run. You have documented expected defects, exclusions, and KPI formulas.

5. Applications to open

Application	How to open it	Why it is open
Databricks notebook 10	Workspace.	Run/store blocking quality checks.
Databricks SQL editor	Quality/Gold/Silver/Bronze.	Inspect results and reconciliation.
VS Code/PowerShell	Repository root.	Run pytest and structural checks.

Application	How to open it	Why it is open
Testing strategy	Open docs/testing_strategy.md.	Map risk to tests and gates.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
python -m pytest -q	Runs unit/integration/sample quality/reconciliation tests that require no paid infrastructure.	Local code/fixtures must pass before remote publication logic.
python -m scripts.validation.validate_sql_dialects; python -m scripts.validation.validate_notebooks; python -m scripts.validation.scan_secrets	Checks SQL headers, notebook syntax/JSON, and common secret patterns.	Structural/security defects can break or expose the project before data runs.
SELECT check_name, actual_value, expected_value, operator, status, required_flag, checked_at_utc	Displays stored batch quality results.	A notebook success banner is not durable evidence.
SELECT status, required_flag, COUNT(*) AS checks	Summarizes check outcomes.	Supports a monitoring KPI without hiding failures.
SELECT MAX(d.full_date) AS latest_sales_date, current_date() AS run_date, datediff(current_date(), MAX(d.full_date)) AS age_days	Calculates sales freshness age.	Row validity does not prove data is current.

Layer reconciliation is not always equality

- Source = Bronze for readable raw rows.
- Bronze = Silver trusted + quarantine + deterministic duplicate losers (with categories documented).
- Silver = Gold for event rows after dimension enrichment; dimensions can have history/unknown rows so their counts differ by design.
- Gold = serving warehouse after publication.
- Gold KPI = Power BI measure under identical filters.

Quality gate failure test

A gate is unproven until a required failure blocks publication. Use a controlled disposable threshold or copied test table, capture the failure/dependency skip, then restore and repair. Never leave the repository configured to fail or lower the test just to get green.

MY TASK

Expand the quality notebook/test results to cover all required verification gates, demonstrate a blocked publication and successful repair, and document owner/action for every rule.

STARTER SKELETON

```
# TODO(USER): reusable reconciliation record
def reconcile(name: str, source_value: float, target_value: float, tolerance: float = 0.0):
```

```

difference = target_value - source_value
status = "PASS" if abs(difference) <= tolerance else "FAIL"
return (batch_id, name, source_value, target_value, difference, tolerance, status, True)

# TODO(USER): add rows for counts, quantity, revenue, profit, and quarantine categories.
# TODO(USER): write to quality.reconciliation_results and fail on required FAIL.

```

Acceptance criteria: The valid batch has stored passing required tests; a controlled failure blocks publication; repair succeeds without duplication; every required project gate has a test/evidence owner.

HINT 1 — CONCEPT

Start from risk register: write the test that catches each high-impact risk.

HINT 2 — PSEUDOCODE

Represent checks as data rows, then filter required failures and raise once after storing results.

HINT 3 — NEAR-COMPLETE PATTERN

Use in-workbook record pattern and extend table checks/reconciliations systematically.

13. Expected files or output

- Local validation pass evidence.
- Comprehensive quality.test_results.
- Reconciliation table/report.
- Failed-gate run with publication skipped.
- Repaired successful run.
- Rule ownership/action matrix.

14. How to verify

- No required fail in publishable batch.
- Failure run actually prevents dependent task.
- Quality results include batch/timestamp/actual/expected/status.
- Quarantine is visible and reconciled.
- Freshness is tested against expected source date semantics.
- Schema drift test has approved schema contract.

15. Automated tests

- All matrix tests from docs/testing_strategy.md.
- Controlled failure and repair.
- Duplicate rerun.
- Source-to-Gold revenue.
- SCD2 behavior.
- Publication dependency.
- Semantic validation later.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
All tests pass suspiciously	Tests may not cover data/risk or filter wrong batch.	Print batch, counts, intentionally fail one rule.	Add negative test and verify gate path.	Controlled failure blocks.
Freshness always fails	Synthetic max date differs from today's real date.	Inspect expected source data date/config.	Test against batch/source expected date or label historical fixture; do not fabricate freshness.	Rule meaning correct.
Reconciliation count mismatch	Dedup/quarantine/history rules not included.	Break difference into categorized outcomes.	Use rule-specific equation rather than forcing equality.	Difference explained.

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
Test results duplicate on re-run	Append same batch/check without replacement/merge.	Group by batch/check.	Delete/merge same batch check rows before insert or add attempt ID/current view.	Monitoring shows intended latest attempt.
Publication ran despite FAIL	Dependency not configured or task result ignored.	Inspect Job graph/run dependencies.	Make publish depend on quality task success; raise exception on required fail.	Publish skipped.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why is a green test suite not automatically trustworthy?
2. How does reconciliation differ across layer boundaries?
3. Why can freshness be tricky with a historical synthetic fixture?
4. What proves a quality gate works?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which type of failed check must block publication?
2. Why store actual and expected values, not only PASS?
3. What should happen to a same-batch quality rerun?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture valid result table, controlled failed Job task with publish skipped, and repaired successful run. Show exact batch IDs and redact account details.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
test: add blocking data quality and reconciliation gates
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Local tests pass — [STATUS]

☐

All dimension/fact rules stored — [STATUS]

☐

Layer reconciliations complete — [STATUS]

☐

Freshness/schema/quarantine monitored — [STATUS]

☐

Controlled gate failure demonstrated — [STATUS]

☐

Publication blocked — [STATUS]

☐

Repair pass and rerun stability verified — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-13. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-13.

Next phase: Phase 14 creates the full Lakeflow Job in the UI and version control with parameters, dependencies, retries, and run operations.

Required action cards

Action 13.2.1 — Open the test matrix and identify which damaging failure each test catches. Remove/replace tests that have no

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Open the test matrix and identify which damaging failure each test catches. Remove/replace tests that have no . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open the test matrix and identify which damaging failure each test catches. Remove/replace tests that have no decision consequence.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Open the test matrix and identify which damaging failure each test catches. Remove/replace tests that have no decision consequence.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 13 lesson index](#)

Action 13.2.2 — Run local Python unit, data-quality, reconciliation, notebook, SQL dialect, secret, and link validations.

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run local Python unit, data-quality, reconciliation, notebook, SQL dialect, secret, and link validations. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Run local Python unit, data-quality, reconciliation, notebook, SQL dialect, secret, and link validations.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

Run local Python unit, data-quality, reconciliation, notebook, SQL dialect, secret, and link validations.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

Action 13.2.7 — Create a disposable controlled failure: temporarily set a required threshold below the observed valid value or

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Create a disposable controlled failure: temporarily set a required threshold below the observed valid value or. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Create a disposable controlled failure: temporarily set a required threshold below the observed valid value or add a copied duplicate test row. Run the gate and verify task fails. Do not corrupt the canonical Gold table without a rollback plan.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 7****Action**

Create a disposable controlled failure: temporarily set a required threshold below the observed valid value or add a copied duplicate test row. Run the gate and verify task fails. Do not corrupt the canonical Gold table without a rollback plan.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 13 lesson index](#)

Action 13.2.8 — Verify publication does not run in the Job dependency graph when gate fails. Capture run evidence.

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Verify publication does not run in the Job dependency graph when gate fails. Capture run evidence. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Verify publication does not run in the Job dependency graph when gate fails. Capture run evidence.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 8

Action

Verify publication does not run in the Job dependency graph when gate fails. Capture run evidence.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

Action 13.2.10 — Create a reconciliation result that compares source/Bronze/Silver/Gold row counts and revenue with rule-specif

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Create a reconciliation result that compares source/Bronze/Silver/Gold row counts and revenue with rule-specif. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Create a reconciliation result that compares source/Bronze/Silver/Gold row counts and revenue with rule-specific explanations rather than expecting every raw count to equal trusted count.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 10

Action

Create a reconciliation result that compares source/Bronze/Silver/Gold row counts and revenue with rule-specific explanations rather than expecting every raw count to equal trusted count.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 13 lesson index](#)

Action 13.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m pytest -q
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m pytest -q` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `pytest` the Python test runner; `-q` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.2.C2 — Windows PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.validation.validate_sql_dialects; python -m scripts.validation.validate_notebooks; python -m scripts.validation.scan_secrets
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** python -m scripts.validation.validate_sql_dialects; python -m scripts.validation.validate_notebooks; python -m scripts.validation.scan_secrets — python invokes Python when that command name is registered; -m asks Python to run an installed module; scripts.validation.validate_sql_dialects is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; python invokes Python when that command name is registered; -m asks Python to run an installed module; scripts.validation.validate_notebooks is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; python invokes Python when that command name is registered; -m asks Python to run an installed module; scripts.validation.scan_secrets is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.2.C3 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT check_name, actual_value, expected_value, operator, status, required_flag, checked_at_utc
FROM northstar_retail.quality.test_results
WHERE batch_id='EXT-YYYYMMDDTHMMSSZ'
ORDER BY status DESC, check_name;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT check_name, actual_value, expected_value, operator, status, required_flag, checked_at_utc` — `SELECT` requests data without changing it unless combined with a modifying statement; `check_name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual_value` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `expected_value` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `operator` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `status` shows tracked, staged, modified, and untracked work; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `required_flag` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.
- **Line 2:** `FROM northstar_retail.quality.test_results` — `FROM` identifies the source table or query; `northstar_retail.quality.test_results` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ'` — `WHERE` filters rows to those meeting a condition; `batch_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `'EXT-YYYYMMDDTHHMMSSZ'` is a quoted literal; the quotation marks preserve spaces or mark text
- **Line 4:** `ORDER BY status DESC, check_name;` — `ORDER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `status` shows tracked, staged, modified, and untracked work; `DESC` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `check_name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.2.C4 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT status, required_flag, COUNT(*) AS checks
FROM northstar_retail.quality.test_results
WHERE batch_id='EXT-YYYYMMDDTHMMSSZ'
GROUP BY status, required_flag;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT status, required_flag, COUNT(*) AS checks` — `SELECT` requests data without changing it unless combined with a modifying statement; `status` shows tracked, staged, modified, and untracked work; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `required_flag` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `checks` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `FROM northstar_retail.quality.test_results` — `FROM` identifies the source table or query; `northstar_retail.quality.test_results` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `WHERE batch_id='EXT-YYYYMMDDTHHMMSSZ'` — `WHERE` filters rows to those meeting a condition; `batch_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `'EXT-YYYYMMDDTHHMMSSZ'` is a quoted literal; the quotation marks preserve spaces or mark text
- **Line 4:** `GROUP BY status, required_flag;` — `GROUP` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `status` shows tracked, staged, modified, and untracked work; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `required_flag` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.2.C5 — Databricks SQL editor

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT MAX(d.full_date) AS latest_sales_date, current_date() AS run_date, datediff(current_date(), MAX(d.full_date)) AS age_days
FROM northstar_retail.gold.fact_sales f
JOIN northstar_retail.gold.dim_date d ON d.date_key=f.order_date_key;
```

Where to enter it:

Databricks SQL editor. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT MAX(d.full_date) AS latest_sales_date, current_date() AS run_date, datediff(current_date(), MAX(d.full_date)) AS age_days — SELECT requests data without changing it unless combined with a modifying statement; MAX is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; d.full_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-

specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; latest_sales_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; current_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; run_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

- **Line 2:** FROM northstar_retail.gold.fact_sales f — FROM identifies the source table or query; northstar_retail.gold.fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; f is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** JOIN northstar_retail.gold.dim_date d ON d.date_key=f.order_date_key; — JOIN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; northstar_retail.gold.dim_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; d is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; ON is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; d.date_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; f.order_date_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 13.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 13 starting-screen checklist and re-verify the active context.

Lesson 13.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 13 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — databricks/

Exact folder name: databricks

Exact parent: repository root

Why it is needed now: Phase 13 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: databricks.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 13.D1.1 — Create the folder databricks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\databricks" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\databricks" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\databricks" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/

Exact folder name: `sql`

Exact parent: `repository root`

Why it is needed now: Phase 13 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `sql`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 13.D2.1 — Create the folder `sql`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql"` is a path, relative location,

branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql" -PathType Container` and require True.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql" -PathType Container`.
2. Require the output True before creating a child file.

3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — tests/

Exact folder name: tests

Exact parent: repository root

Why it is needed now: Phase 13 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: tests.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 13.D3.1 — Create the folder tests

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\tests" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\tests" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\tests"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path tests one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: reconciliation.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 13.D7.1 — Create the folder tests/reconciliation

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\tests\reconciliation" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\tests\reconciliation" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\tests\reconciliation` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\tests\reconciliation" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\tests\reconciliation" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run Test-Path ".\tests\reconciliation" -PathType Container.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/databricks/quality/

Exact folder name: quality

Exact parent: sql/databricks

Why it is needed now: Phase 13 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path sql/databricks one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: quality.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 13.D8.1 — Create the folder sql/databricks/quality

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql\databricks\quality" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\sql\databricks\quality" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\sql\databricks\quality` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\sql\databricks\quality" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\databricks\quality" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\databricks\quality" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — databricks/notebooks/10_data_quality.py

Exact filename: `10_data_quality.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `databricks/notebooks` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 13.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `databricks/notebooks` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `10_data_quality.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `10_data_quality.py` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 13.F1.1 — Create the file `databricks/notebooks/10_data_quality.py` from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\databricks\notebooks\10_data_quality.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\databricks\notebooks\10_data_quality.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\notebooks\10_data_quality.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\databricks\notebooks\10_data_quality.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "databricks/notebooks/10_data_quality.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `databricks/notebooks`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `databricks/notebooks/10_data_quality.py`.
3. In PowerShell at the repository root, run `Test-Path ".\databricks\notebooks\10_data_quality.py"` and require `True`.

4. Run `git status --short -- "databricks/notebooks/10_data_quality.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for databricks/notebooks/10_data_quality.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: databricks/notebooks/10_data_quality.py

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 13.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Databricks notebook source
# Northstar Retail End-to-End Data Platform
# This file is a Git-friendly Databricks source notebook.
# Track A reads files that you manually uploaded to a Unity Catalog volume.
# It never attempts to reach SQL Server or PostgreSQL on localhost.

# COMMAND -----
# MAGIC %md
# MAGIC # 10 – Data-quality gate
# MAGIC A failed required check raises an exception so publication cannot run.

# COMMAND -----
from pyspark.sql import functions as F
for name, default in {"catalog": "northstar_retail", "gold_schema": "gold", "quality_schema": "quality", "batch_id": "MANUAL-REPLACE-ME"}.items():

[Back to the Phase 13 lesson index](#)

File introduction — `sql/databricks/quality/01_quality_gate.sql`

Exact filename: `01_quality_gate.sql`

Filename extension: `.sql`. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/databricks/quality relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 13.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/databricks/quality one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 01_quality_gate.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 01_quality_gate.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 13.F2.1 — Create the file sql/databricks/quality/01_quality_gate.sql from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\databricks\quality\01_quality_gate.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\databricks\quality\01_quality_gate.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\databricks\quality\01_quality_gate.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\databricks\quality\01_quality_gate.sql" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/databricks/quality/01_quality_gate.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/databricks/quality`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/databricks/quality/01_quality_gate.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\databricks\quality\01_quality_gate.sql"` and require True.
4. Run `git status --short -- "sql/databricks/quality/01_quality_gate.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/databricks/quality/01_quality_gate.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/databricks/quality/01_quality_gate.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 13.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: Databricks SQL / Spark SQL
-- These assertion queries should each return zero failed rows.
SELECT COUNT(*) AS duplicate_order_item_rows
FROM (
  SELECT order_item_id FROM IDENTIFIER(:fact_sales_table)
  GROUP BY order_item_id HAVING COUNT(*) > 1
);

SELECT COUNT(*) AS invalid_revenue_identity_rows
FROM IDENTIFIER(:fact_sales_table)
WHERE abs(net_sales_amount - (gross_sales_amount - discount_amount)) > 0.01;
```

Line-by-line explanation

- **Line 1:** `-- Dialect: Databricks SQL / Spark SQL` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `-- These assertion queries should each return zero failed rows.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 3:** `SELECT COUNT(*) AS duplicate_order_item_rows` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-

specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; duplicate_order_item_rows is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

[Back to the Phase 13 lesson index](#)

File introduction — tests/data_quality/test_sample_quality_fixture.py

Exact filename: test_sample_quality_fixture.py

Filename extension: .py. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: tests/data_quality relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source

SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 13.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in tests/data_quality one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: test_sample_quality_fixture.py.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled test_sample_quality_fixture.py and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 13.F3.1 — Create the file tests/data_quality/test_sample_quality_fixture.py from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\tests\data_quality\test_sample_quality_fixture.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\tests\data_quality\test_sample_quality_fixture.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\tests\data_quality\test_sample_quality_fixture.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\tests\data_quality\test_sample_quality_fixture.py" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "tests/data_quality/test_sample_quality_fixture.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `tests/data_quality`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `tests/data_quality/test_sample_quality_fixture.py`.
3. In PowerShell at the repository root, run `Test-Path ".\tests\data_quality\test_sample_quality_fixture.py"` and require True.
4. Run `git status --short -- "tests/data_quality/test_sample_quality_fixture.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `tests/data_quality/test_sample_quality_fixture.py`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `tests/data_quality/test_sample_quality_fixture.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 13.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
from __future__ import annotations

import json
from pathlib import Path

import pandas as pd

ROOT = Path("datasets/sample")

def test_controlled_dirty_data_is_present() -> None:
    customers = pd.read_csv(ROOT / "sqlserver/customers.csv")
    items = pd.read_csv(ROOT / "sqlserver/order_items.csv")
    expected = json.loads((ROOT / "metadata/expected_quality_issues.json").read_text())["configured_issue_counts"]
    assert customers.email.isna().sum() >= expected["null_emails"]
    assert (items.quantity <= 0).sum() >= expected["impossible_quantities"]
    assert customers.customer_number.duplicated(keep=False).sum() >= expected["duplicate_business_keys"]

def test_no_unexpected_order_orphans() -> None:
    customers = pd.read_csv(ROOT / "sqlserver/customers.csv")
    orders = pd.read_csv(ROOT / "sqlserver/orders.csv")
    assert not (set(orders.customer_id) - set(customers.customer_id))
```

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in tests/reconciliation one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: test_sample_reconciliation.py.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled test_sample_reconciliation.py and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 13.F4.1 — Create the file tests/reconciliation/test_sample_reconciliation.py from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\tests\reconciliation\test_sample_reconciliation.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\tests\reconciliation\test_sample_reconciliation.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\tests\reconciliation\test_sample_reconciliation.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\tests\reconciliation\test_sample_reconciliation.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "tests/reconciliation/test_sample_reconciliation.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `tests/reconciliation`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `tests/reconciliation/test_sample_reconciliation.py`.
3. In PowerShell at the repository root, run `Test-Path ".\tests\reconciliation\test_sample_reconciliation.py"` and require `True`.
4. Run `git status --short -- "tests/reconciliation/test_sample_reconciliation.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for tests/reconciliation/test_sample_reconciliation.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `tests/reconciliation/test_sample_reconciliation.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 13.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
from __future__ import annotations

from pathlib import Path

import pandas as pd

ROOT = Path("datasets/sample")

def test_valid_line_revenue_formula_is_reproducible() -> None:
    items = pd.read_csv(ROOT / "sqlserver/order_items.csv")
    valid = items[items.quantity > 0].copy()
    valid["net"] = valid.quantity * valid.unit_price - valid.discount_amount
    valid["profit"] = valid["net"] - valid.quantity * valid.unit_cost
    assert valid["net"].notna().all()
    assert abs(valid["profit"].sum() - (valid["net"].sum() - (valid.quantity * valid.unit_cost).sum())) < 0.01

def test_inventory_snapshot_grain_is_unique() -> None:
    snapshot = pd.read_csv(ROOT / "sqlserver/inventory_snapshots.csv")
    assert not snapshot.duplicated(["snapshot_date", "store_id", "product_id"]).any()
```

Line-by-line explanation

described in the surrounding explanation; ([is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "snapshot_date" is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "store_id" is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; "product_id" is a quoted literal; the quotation marks preserve spaces or mark text;]) . is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; any is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

[Back to the Phase 13 lesson index](#)

What your screen should look like now

- Every Phase 13 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 13.3 completion checklist

☐

databricks/notebooks/10_data_quality.py was created by me, saved, located correctly, and inspected — [STATUS]

☐

sql/databricks/quality/01_quality_gate.sql was created by me, saved, located correctly, and inspected — [STATUS]

☐

tests/data_quality/test_sample_quality_fixture.py was created by me, saved, located correctly, and inspected — [STATUS]

☐

tests/reconciliation/test_sample_reconciliation.py was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 13.4](#) and recheck the root and branch.

Lesson 13.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Quality test 1 — required files and manifest completeness

Risk: A batch can be incomplete while later code still finds some files.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T1 — Implement and prove the required files and manifest completeness quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the required files and manifest completeness quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for required files and manifest completeness.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for required files and manifest completeness.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed required files and manifest completeness from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 2 — manifest checksum match

Risk: A file can be changed, truncated, or replaced after generation.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T2 — Implement and prove the manifest checksum match quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the `manifest checksum match` quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or `databricks/notebooks/10_data_quality.py`.
3. TYPE THIS: Build the smallest test query or assertion for `manifest checksum match`.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for manifest checksum match.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Teaching assertion

```
def test_manifest_checksum_match():
    actual = run_quality_check("manifest checksum match")
    assert actual["status"] == "PASS", actual
```

Line-by-line explanation

- **Line 1:** `def test_manifest_checksum_match():` — `def` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `test_manifest_checksum_match` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `actual = run_quality_check("manifest checksum match")` — `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `run_quality_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"manifest checksum match"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `assert actual["status"] == "PASS", actual` — `assert` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"status"` is a quoted literal; the quotation marks preserve spaces or mark text; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `==` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"PASS"` is a quoted literal; the quotation marks preserve spaces or mark text; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Controlled-failure record

- Valid run ID/batch: [ENTER]
- Valid result: [ENTER ACTUAL + EXPECTED + PASS]
- Toy defect introduced: [DESCRIBE]
- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed `manifest_checksum_match` from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 3 — Bronze source-to-target row reconciliation

Risk: Ingestion can omit or duplicate raw records.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T3 — Implement and prove the Bronze source-to-target row reconciliation quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the Bronze source-to-target row reconciliation quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed Bronze source-to-target row reconciliation from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 4 — required-key null check

Risk: Rows without required identifiers cannot be joined or deduplicated reliably.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T4 — Implement and prove the required-key null check quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the required-key null check quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed required-key null check from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 5 — business-key duplicate check

Risk: Duplicates can multiply facts or create ambiguous dimension matches.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T5 — Implement and prove the business-key duplicate check quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the business-key duplicate check quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for business-key duplicate check.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for business-key duplicate check.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

- **Line 3:** `assert actual["status"] == "PASS", actual` — `assert` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"status"` is a quoted literal; the quotation marks preserve spaces or mark text; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `==` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"PASS"` is a quoted literal; the quotation marks preserve spaces or mark text; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Controlled-failure record

- Valid run ID/batch: [ENTER]
- Valid result: [ENTER ACTUAL + EXPECTED + PASS]
- Toy defect introduced: [DESCRIBE]
- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed `business-key duplicate check` from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 6 — foreign-key orphan check

Risk: Child rows can reference parents that do not exist.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value,

expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T6 — Implement and prove the foreign-key orphan check quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the foreign-key orphan check quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for foreign-key orphan check.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for foreign-key orphan check.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Teaching assertion

```
def test_foreign_key_orphan_check():
    actual = run_quality_check("foreign-key orphan check")
    assert actual["status"] == "PASS", actual
```

Line-by-line explanation

- **Line 1:** `def test_foreign_key_orphan_check():` — `def` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `test_foreign_key_orphan_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `actual = run_quality_check("foreign-key orphan check")` — `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `run_quality_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"foreign-key orphan check"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `assert actual["status"] == "PASS", actual` — `assert` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"status"` is a quoted literal; the quotation marks preserve spaces or mark text; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `==` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"PASS"` is a quoted literal; the quotation marks preserve spaces or mark text; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Controlled-failure record

- Valid run ID/batch: [ENTER]
- Valid result: [ENTER ACTUAL + EXPECTED + PASS]
- Toy defect introduced: [DESCRIBE]
- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed foreign-key orphan check from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 7 — accepted-plus-rejected reconciliation

Risk: Cleaning can silently discard rows.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T7 — Implement and prove the accepted-plus-rejected reconciliation quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the accepted-plus-rejected reconciliation quality test. This is one bounded construction or inspection task.

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed `accepted-plus-rejected_reconciliation` from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 8 — SCD2 current-row uniqueness

Risk: Multiple current versions make fact lookups ambiguous.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T8 — Implement and prove the SCD2 current-row uniqueness quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the SCD2 current-row uniqueness quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed SCD2 current-row uniqueness from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 9 — SCD2 effective-window overlap

Risk: Overlapping history windows can resolve one event to multiple versions.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T9 — Implement and prove the SCD2 effective-window overlap quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the SCD2 effective-window overlap quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for SCD2 effective-window overlap.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for SCD2 effective-window overlap.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

- **Line 1:** `def test_scd2_effective_window_overlap():` — `def` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `test_scd2_effective_window_overlap` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is

a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 2:** `actual = run_quality_check("SCD2 effective-window overlap")` — `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `run_quality_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"SCD2 effective-window overlap"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `assert actual["status"] == "PASS", actual` — `assert` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"status"` is a quoted literal; the quotation marks preserve spaces or mark text; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `==` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"PASS"` is a quoted literal; the quotation marks preserve spaces or mark text; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Controlled-failure record

- Valid run ID/batch: [ENTER]
- Valid result: [ENTER ACTUAL + EXPECTED + PASS]
- Toy defect introduced: [DESCRIBE]
- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed SCD2 effective-window overlap from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 10 — fact grain duplicate check

Risk: A repeated business event overstates counts and amounts.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T10 — Implement and prove the fact grain duplicate check quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the fact `grain duplicate check` quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or `databricks/notebooks/10_data_quality.py`.
3. TYPE THIS: Build the smallest test query or assertion for `fact grain duplicate check`.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or `databricks/notebooks/10_data_quality.py`.
3. TYPE THIS: Build the smallest test query or assertion for `fact grain duplicate check`.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 13 lesson index](#)

Teaching assertion

```
def test_freshness_and_batch_completion_check():
    actual = run_quality_check("freshness and batch-completion check")
    assert actual["status"] == "PASS", actual
```

Line-by-line explanation

- **Line 1:** `def test_freshness_and_batch_completion_check():` — `def` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `test_freshness_and_batch_completion_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `actual = run_quality_check("freshness and batch-completion check")` — `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `run_quality_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"freshness and batch-completion check"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `assert actual["status"] == "PASS", actual` — `assert` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"status"` is a quoted literal; the quotation marks preserve spaces or mark text; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `==` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"PASS"` is a quoted literal; the quotation marks

preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; actual is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Controlled-failure record

- Valid run ID/batch: [ENTER]
- Valid result: [ENTER ACTUAL + EXPECTED + PASS]
- Toy defect introduced: [DESCRIBE]
- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed freshness and batch-completion check from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

Quality test 14 — warehouse publication gate

Risk: Unverified Gold data can reach reporting.

Passing means: The actual result meets the stated threshold or invariant for the exact batch and layer.

Failing means: Data or metadata cannot be trusted for its next use; the result must identify the entity, batch, actual value, expected value, severity, and rule ID.

Pipeline behavior: A critical integrity, reconciliation, duplicate, or required-field failure blocks publication. A warning-level issue is recorded and reviewed without being mislabeled as success.

Action 13.4.T14 — Implement and prove the warehouse publication gate quality test

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Implement and prove the warehouse publication gate quality test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for warehouse publication gate.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.

7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. LOOK FOR: Read the risk statement and write what a passing and failing result mean before code.
2. CLICK: Open the named local test file or databricks/notebooks/10_data_quality.py.
3. TYPE THIS: Build the smallest test query or assertion for warehouse publication gate.
4. PRESS: Run it against the valid sample or current verified batch.
5. LOOK FOR: Require a PASS result with actual and expected values stored.
6. TYPE THIS: Introduce a tiny toy failure in a disposable fixture or temporary DataFrame; do not corrupt verified project data.
7. PRESS: Run the test again.
8. LOOK FOR: Require a controlled failure and verify downstream publication is skipped when the test is blocking.
9. TYPE THIS: Remove or repair the toy failure.
10. PRESS: Rerun and require PASS.
11. DO NOT CONTINUE UNTIL: You have evidence for valid, failed, and repaired behavior.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Teaching assertion

```
def test_warehouse_publication_gate():
    actual = run_quality_check("warehouse publication gate")
    assert actual["status"] == "PASS", actual
```

Line-by-line explanation

- **Line 1:** `def test_warehouse_publication_gate():` — `def` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `test_warehouse_publication_gate` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `actual = run_quality_check("warehouse publication gate")` — `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `run_quality_check` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"warehouse publication gate"` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `assert actual["status"] == "PASS", actual` — `assert` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"status"` is a quoted literal; the quotation marks preserve spaces or mark text; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `==` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `"PASS"` is a quoted literal; the quotation marks preserve spaces or mark text; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `actual` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Controlled-failure record

- Valid run ID/batch: [ENTER]
- Valid result: [ENTER ACTUAL + EXPECTED + PASS]
- Toy defect introduced: [DESCRIBE]
- Failed result: [ENTER ACTUAL + EXPECTED + FAIL]
- Downstream task behavior: [SKIPPED/BLOCKED/OTHER + EVIDENCE]
- Repair made: [DESCRIBE]
- Repaired result: [ENTER]

Troubleshooting

If a test passes when the toy defect exists, suspect that the query filters the defect out, reads the wrong batch/table, compares the wrong grain, or treats null incorrectly. Print the test population and a failing example. Do not weaken the threshold merely to make the status green.

Interview-ready explanation

"I designed `warehouse_publication_gate` from a business/data risk, stored actual and expected values, demonstrated a controlled failure, and verified that the blocking behavior protected downstream publication."

What your screen should look like now

- The new Phase 13 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 13.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 13.5](#).

Lesson 13.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 13 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Verification before automation

Question:

Should the phase prioritize a visible manual verification or jump directly to automation?

Options considered:

- Manual verification first, then automation.
- Automation without a known-good baseline.
- Manual operation forever.

Beginner path selected:

Establish one verified manual baseline and then automate repeatable checks.

Why this path was selected:

A known-good example makes failures interpretable and prevents automation from hiding a wrong assumption.

Tradeoff:

The first run takes longer.

What a company might do instead:

Teams often pair infrastructure as code and automated tests with controlled bootstrap and acceptance procedures.

How to explain this in an interview:

I established a verified baseline, then encoded the same contract in tests and orchestration so automation preserved meaning rather than just speed.

Design decision — Test framework choices

Question:

Which testing tools should validate Python logic, data quality, SQL contracts, and repository structure?

Options considered:

- pytest plus explicit SQL/Databricks quality queries and reconciliation tables.
- Only manual inspection.

- A single vendor-specific data-testing framework for every layer.

Beginner path selected:

Use pytest for local Python/fixture/repository tests and explicit SQL or PySpark checks for database and lakehouse contracts.

Why this path was selected:

The combination is transparent, free, CI-friendly, and teaches the difference between unit, contract, data-quality, and reconciliation tests without hiding logic behind one tool.

Tradeoff:

The learner maintains more than one testing style and must standardize result metadata manually.

What a company might do instead:

A company might add Great Expectations, Soda, dbt tests, Deequ, contract registries, observability platforms, and environment-specific integration suites.

How to explain this in an interview:

I matched the test tool to the execution layer: pytest for deterministic local logic and executable SQL/PySpark gates for live data contracts, all tied to batch evidence.

If you see Result A

Required tests record PASS with expected and actual values and permit publication. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

A blocking rule records FAIL and downstream publication remains skipped. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: VS Code tests, Databricks notebooks, Catalog Explorer, and Job task output.

Window/panel: Show valid test, controlled blocking failure, and repaired result.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase13_build-data-quality-reconciliation-and-failure-gates_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 13's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 13 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 13.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.
- `MM` means a staged version exists and the file has additional unstaged edits.
- `A` means staged as a new file.
- `D` means deletion; stop and investigate unless deletion is deliberate.
- `R` means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 13.5.G4 — Inspect the unstaged diff for databricks/notebooks/10_data_quality.py

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "databricks/notebooks/10_data_quality.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "databricks/notebooks/10_data_quality.py"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/notebooks/10_data_quality.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.5.G5 — Stage only the reviewed file databricks/notebooks/10_data_quality.py

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "databricks/notebooks/10_data_quality.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "databricks/notebooks/10_data_quality.py"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/notebooks/10_data_quality.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 13.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.5.G7 — Create the Phase 13 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "test: add blocking quality and reconciliation gates"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "test: add blocking quality and reconciliation gates"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"test: add blocking quality and reconciliation gates"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Action 13.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 13 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message test: add blocking quality and reconciliation gates and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 13.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 13 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 13 created the verified boundary described by **Build data-quality, reconciliation, and failure gates**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 13 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** PLANNED, CREATED BY USER, and RUN BY USER describe earlier states; only inspected evidence supports verification.

What I can now explain without help:

[WRITE YOUR ANSWER]

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 13.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 14 connects them in dependency order and proves repair behavior.

Phase 13 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 14 — Create and operate a multi-task Databricks Job

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: A successful, idempotent Databricks Job run.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 15 exports only verified Gold results and loads them into the local warehouse.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 14 lesson index

1. [Lesson 14.1 — Understand the phase and starting screen](#)
2. [Lesson 14.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 14.3 — Create and understand the phase files](#)
4. [Lesson 14.4 — Build and validate required objects](#)
5. [Lesson 14.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 14.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Databricks Jobs & Pipelines, notebook task pages, run history, and notifications settings.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 14 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 13 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 14 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Databricks Jobs & Pipelines, notebook task pages, run history, and notifications settings. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 14 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 14 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 14 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 14.1 completion checklist

☐

I read why Phase 14 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 14.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 14 lesson index](#)

Lesson 14.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 14 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A parameterized Lakeflow Job containing environment validation, three Bronze tasks, four Silver domain tasks, Gold dimensions, Gold facts, quality gate, publication, and final reconciliation, with correct dependencies, compute, retries, timeouts, notifications, schedule decision, repair-run procedure, and a version-controlled definition.

2. Why it matters

A set of notebooks becomes a pipeline only when execution order, shared parameters, failure behavior, retries, and operational evidence are controlled. Orchestration prevents a user from accidentally publishing before upstream tasks or tests finish.

3. Words to know

Term	Plain-language definition
Job	Named orchestrated workflow.
Task	One executable unit inside a Job.
Dependency	Task that must succeed before another starts.
Parameter	Runtime value passed to tasks, such as batch ID.
Retry	Automatic rerun for likely transient failure.
Timeout	Maximum task/job runtime before failure.
Notification	Message on selected run events.
Schedule	Time/trigger for starting a Job.
Repair run	Rerun failed/skipped downstream tasks within an existing run.
Run history	Stored status, timing, parameters, logs, task graph.
Concurrent run	Multiple Job instances executing at once.
Job cluster/serverless	Compute selected for Job tasks; availability varies.
Declarative Automation Bundle	Current Databricks version-controlled deployment packaging; formerly Asset Bundles in older naming.
Task dependency diagram	Visual execution graph.

4. What must already be completed

Notebooks 00–12 exist in workspace; manual runs through quality are understood; exact parameter names are consistent; current workspace jobs/compute limitations are reviewed.

5. Applications to open

Application	How to open it	Why it is open
Databricks Jobs & Pipelines / Workflows UI	Left navigation current equivalent.	Create/configure/run Job.
Workspace notebooks	Open task files.	Confirm paths/parameters.

Application	How to open it	Why it is open
VS Code	Open job_definition.example.yml and task map.	Version-control graph.
Email/notification destination	Only if appropriate and permitted.	Test notifications without exposing data.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
batch_id = EXT-YYYYMMDDTHHMMSSZ	Selects one uploaded extraction batch for every task.	A Job without a concrete batch can mix/default wrong input.
print({name: dbutils.widgets.get(name) for name in ["catalog", "batch_id"]})	Shows key task parameters.	Detects parameter propagation failure.
python -c "import yaml, pathlib; p=yaml.safe_load(pathlib.Path('databricks/jobs/job_definition.example.yml').read_text()); print([t['task_key'] for t in p['resources']['jobs']['northstar_retail_daily']['tasks']])"	Parses job YAML and lists tasks.	Version-controlled definition must be valid YAML and complete.
python -m pytest -q tests\integration\test_repository_contract.py	Checks every YAML notebook path exists and Gold dictionary contract.	Prevents stale orchestration references.

Retry policy

Retry transient storage/compute/network availability failures a small number of times with delay. Do not repeatedly retry deterministic schema, permission, missing-path, or quality assertion failures; retries waste quota and hide diagnosis.

Scheduling Track A

Because the local extraction/upload is manual, an automatic daily Job can find no new batch or rerun an old one. The beginner default is manual run after upload. An advanced readiness trigger reads a control object/manifest and selects an unprocessed batch safely.

Version control

The example YAML captures logical resources and real repository-relative notebook paths. A deployable Databricks bundle additionally needs workspace target configuration and supported CLI authentication; keep that optional until the UI Job is verified.

MY TASK

Build the entire Job in the UI, align it to the YAML and dependency diagram, run a valid batch, demonstrate blocked publication and repair, and document manual-versus-scheduled trigger decision.

STARTER SKELETON

```
resources:
  jobs:
```

```
northstar_retail_daily:
  name: northstar-retail-daily
  max_concurrent_runs: 1
  parameters:
    - name: batch_id
      default: TODO(USER)-REQUIRED
  tasks:
    - task_key: TODO(USER)
      depends_on:
        - task_key: TODO(USER)
      notebook_task:
        notebook_path: ../notebooks/TODOTODO(USER).py
        base_parameters:
          batch_id: "{{job.parameters.batch_id}}"
        max_retries: TODO(USER)
        timeout_seconds: TODO(USER)
# TODO(USER): fill only after building/validating UI graph.
```

Acceptance criteria: UI graph and YAML contain all real notebook tasks/dependencies; all tasks receive same parameters; valid run succeeds; failed gate skips publish; repair succeeds; concurrent/schedule/retry decisions are documented.

HINT 1 — CONCEPT

Start with the final gate chain and work backward to prerequisites.

HINT 2 — PSEUDOCODE

Dependency pseudocode: environment → Bronze parallel → Silver domains → dimensions → facts → quality → publish → reconcile.

HINT 3 — NEAR-COMPLETE PATTERN

Compare every task to in-workbook `job_definition.example.yml` reference, but enter it yourself in UI and verify paths.

13. Expected files or output

- Lakeflow Job graph with 13 tasks.
- Shared parameter set.
- Valid run ID/history.
- Failed/skipped/repair evidence.
- Updated version-controlled YAML/task map.
- Trigger/retry/timeout/notification decision log.

14. How to verify

- Every task path opens a real notebook.
- No task bypasses quality before publication.
- Parallel tasks stay within workspace limits.
- Max concurrent runs 1.
- Run parameters consistent.
- Repair does not duplicate data.
- YAML parses and contract test passes.

15. Automated tests

- Job dependency graph review.
- Valid end-to-end run.
- Controlled failure/skip/repair.
- Same-batch idempotency.
- YAML parsing and path tests.
- Notification test if configured.
- Manual/schedule readiness behavior.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
Notebook path invalid	Workspace Git/import path differs from YAML.	Open task source selector and repository paths.	Point to actual synced notebook; update workspace-neutral mapping.	Task opens/runs.
Parameter default used accidentally	Run dialog not set or task mapping wrong.	Inspect run/task parameters/log output.	Require/validate batch placeholder and pass Job parameters.	All print exact batch.
Retries repeat quality failure	Retry configured for deterministic assertion.	Run attempts/error same each time.	Reduce retry or classify; fix data/code, use repair.	Quota not wasted.
Publish runs too early	Missing/wrong dependency.	Inspect graph edges and run timeline.	Make publish directly depend on successful quality gate.	Failure skips publish.
Schedule reruns old batch	Manual handoff has no readiness selection.	Inspect scheduled parameter/history.	Keep manual or implement processed-batch control/readiness gate.	Each run selects new intended batch.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why set max concurrent runs to one?
2. Which failures deserve automatic retry?
3. Why is a clock schedule risky in Track A?
4. What does a repair run preserve compared with starting blindly?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which task must `publish_gold` depend on?
2. How many parallel Bronze tasks are in the documented graph?
3. What current Databricks term replaces older Asset Bundles naming?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture full task graph, run parameters, successful run history, and controlled failure with publish skipped/repair. Show run ID; redact email if needed.

Save the image under `docs/images/` with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: orchestrate northstar lakeflow job with quality gate
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

All tasks created — [STATUS]

☐

Dependencies match diagram — [STATUS]

☐

Parameters propagate — [STATUS]

☐

Compute/retries/timeouts documented — [STATUS]

☐

Concurrency/schedule decision documented — [STATUS]

☐

Valid run passes — [STATUS]

☐

Failure/skip/repair proven — [STATUS]

☐

YAML/path tests pass — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-14. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-14.

Next phase: Phase 15 exports validated Gold and transactionally publishes it into local SQL Server NorthstarRetail_DW.

Required action cards

Action 14.2.1 — Open databricks/jobs/job_task_map.md and explain every arrow. The graph allows three Bronze tasks in parallel

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Open databricks/jobs/job_task_map.md and explain every arrow. The graph allows three Bronze tasks in parallel. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open databricks/jobs/job_task_map.md and explain every arrow. The graph allows three Bronze tasks in parallel and requires all relevant Silver domains before dimensions.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Open `databricks/jobs/job_task_map.md` and explain every arrow. The graph allows three Bronze tasks in parallel and requires all relevant Silver domains before dimensions.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#)

Action 14.2.2 — In Databricks left navigation open or , choose , name it northstar-retail-daily.

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

In Databricks left navigation open or , choose , name it northstar-retail-daily. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: In Databricks left navigation open **Jobs & Pipelines** or **Workflows**, choose **Create > Job**, name it northstar-retail-daily.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

In Databricks left navigation open **Jobs & Pipelines** or **Workflows**, choose **Create > Job**, name it northstar-retail-daily.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#)

Action 14.2.3 — Add Job parameters for catalog, schemas, volume, and batch_id. Set batch_id default to an unmistakable placeho

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Add Job parameters for catalog, schemas, volume, and batch_id. Set batch_id default to an unmistakable placeho. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Add Job parameters for catalog, schemas, volume, and batch_id. Set batch_id default to an unmistakable placeholder; require a real value at run time.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

Add Job parameters for catalog, schemas, volume, and batch_id. Set batch_id default to an unmistakable placeholder; require a real value at run time.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

I can describe what changed on the screen or filesystem.

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#)

Action 14.2.4 — Add task `environment_check`, type Notebook, select `00_environment_check`, pass parameters with Job parameter

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Add task `environment_check`, type Notebook, select `00_environment_check`, pass parameters with Job parameter. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.

2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Add task `environment_check`, type Notebook, select `00_environment_check`, pass parameters with Job parameter references, and choose available serverless/job compute.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 4

Action

Add task `environment_check`, type Notebook, select `00_environment_check`, pass parameters with Job parameter references, and choose available serverless/job compute.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Action 14.2.5 — Add three Bronze tasks depending on environment_check. Configure at most two retries with a sensible interval

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Add three Bronze tasks depending on environment_check. Configure at most two retries with a sensible interval . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Add three Bronze tasks depending on environment_check. Configure at most two retries with a sensible interval for transient reads; deterministic data/assertion failures should still remain visible.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 5

Action

Add three Bronze tasks depending on environment_check. Configure at most two retries with a sensible interval for transient reads; deterministic data/assertion failures should still remain visible.

Action 14.2.13 — Use the controlled quality failure from Phase 13 to verify skipped publish. Restore and use from the earliest

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Use the controlled quality failure from Phase 13 to verify skipped publish. Restore and use from the earliest . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Use the controlled quality failure from Phase 13 to verify skipped publish. Restore and use **Repair run** from the earliest affected task.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 13****Action**

Use the controlled quality failure from Phase 13 to verify skipped publish. Restore and use **Repair run** from the earliest affected task.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#)

Action 14.2.14 — Compare the UI Job to `job_definition.example.yml`. Update the YAML with actual workspace-neutral logic but ke

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Compare the UI Job to `job_definition.example.yml`. Update the YAML with actual workspace-neutral logic but ke. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Compare the UI Job to `job_definition.example.yml`. Update the YAML with actual workspace-neutral logic but keep secrets/individual paths out. For deployable automation, create a root bundle later using current official Declarative Automation Bundles docs.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 14****Action**

Compare the UI Job to `job_definition.example.yml`. Update the YAML with actual workspace-neutral logic but keep secrets/individual paths out. For deployable automation, create a root bundle later using current official Declarative Automation Bundles docs.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#)

Action 14.2.C1 — Databricks Job run parameter dialog

Application:

Databricks workspace in a web browser

Window or panel:

Databricks Job run parameter dialog

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Text instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Text):

```
batch_id = EXT-YYYYMMDDTHHMMSSZ
```

Where to enter it:

Databricks Job run parameter dialog. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `batch_id = EXT-YYYYMMDDTHHMMSSZ` — `batch_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `EXT-YYYYMMDDTHHMMSSZ` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.2.C2 — Databricks notebook task cell/log

Application:

Databricks workspace in a web browser

Window or panel:

Databricks notebook task cell/log

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Python instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Python):

```
print({name: dbutils.widgets.get(name) for name in ["catalog", "batch_id"]})
```

Where to enter it:

Databricks notebook task cell/log. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `print({name: dbutils.widgets.get(name) for name in ["catalog", "batch_id"]})` — `print` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `{` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `:` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `;` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `dbutils.widgets.get` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `for` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `in` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.2.C3 — Windows PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -c "import yaml, pathlib; p=yaml.safe_load(pathlib.Path('databricks/jobs/job_definition.example.yaml').read_text()); print([t['task_key'] for t in p['resources']['jobs']['northstar_retail_daily']['tasks'])"
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -c "import yaml, pathlib; p=yaml.safe_load(pathlib.Path('databricks/jobs/job_definition.example.yaml').read_text()); print([t['task_key'] for t in p['resources']['jobs']['northstar_retail_daily']['tasks']])"` — `python` invokes Python when that command name is registered; `-c` creates the named branch before switching; `"import yaml, pathlib; p=yaml.safe_load(pathlib.Path('databricks/jobs/job_definition.example.yaml').read_text()); print([t['task_key'] for t in p['resources']['jobs']['northstar_retail_daily']['tasks']])"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.2.C4 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m pytest -q tests\integration\test_repository_contract.py
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m pytest -q tests\integration\test_repository_contract.py` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `pytest` the Python test runner; `-q` is a command option or flag; its exact behavior is defined beside the command; `tests` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `integration` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `test_repository_contract.py` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 14.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 14 starting-screen checklist and re-verify the active context.

Lesson 14.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 14 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — databricks/

Exact folder name: databricks

Exact parent: repository root

Why it is needed now: Phase 14 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: databricks.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 14.D1.1 — Create the folder databricks

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.

6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\databricks" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\databricks" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\databricks" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — databricks/jobs/

Exact folder name: jobs

Exact parent: databricks

Why it is needed now: Phase 14 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path databricks one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: jobs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 14.D2.1 — Create the folder databricks/jobs

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\databricks\jobs" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\databricks\jobs" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\databricks\jobs` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\databricks\jobs" -PathType Container` and require True.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\databricks\jobs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\databricks\jobs" -PathType Container`.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — databricks/jobs/job_definition.example.yml

Exact filename: `job_definition.example.yml`

Filename extension: `.yml`. In this project it identifies human-readable configuration and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `databricks/jobs` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: human-readable configuration for Phase 14.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? Yes—review carefully before Git staging.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `databricks/jobs` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.

6. CLICK: Select **New File**.
7. TYPE THIS: `job_definition.example.yml`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `job_definition.example.yml` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 14.F1.1 — Create the file `databricks/jobs/job_definition.example.yml` from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\databricks\jobs\job_definition.example.yml" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\databricks\jobs\job_definition.example.yml" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\jobs\job_definition.example.yml"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\databricks\jobs\job_definition.example.yml" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "databricks/jobs/job_definition.example.yml"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.

5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under databricks/jobs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with databricks/jobs/job_definition.example.yml.
3. In PowerShell at the repository root, run Test-Path ".\databricks\jobs\job_definition.example.yml" and require True.
4. Run git status --short -- "databricks/jobs/job_definition.example.yml" to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for databricks/jobs/job_definition.example.yml

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: YAML

Exact file: databricks/jobs/job_definition.example.yml

Purpose: human-readable configuration.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 14.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Example version-controlled Lakeflow Job definition.
# Paths are repository-relative and point to files the learner manually creates through this workbook.
# Adapt this file to your workspace or convert it into a root databricks.yml bundle.

File introduction — databricks/jobs/job_task_map.md

Exact filename: `job_task_map.md`

Filename extension: `.md`. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `databricks/jobs` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 14.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in databricks/jobs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `job_task_map.md`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `job_task_map.md` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 14.F2.1 — Create the file `databricks/jobs/job_task_map.md` from PowerShell

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\databricks\jobs\job_task_map.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\databricks\jobs\job_task_map.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\databricks\jobs\job_task_map.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\databricks\jobs\job_task_map.md" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "databricks/jobs/job_task_map.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `databricks/jobs`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `databricks/jobs/job_task_map.md`.
3. In PowerShell at the repository root, run `Test-Path ".\databricks\jobs\job_task_map.md"` and require True.
4. Run `git status --short -- "databricks/jobs/job_task_map.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for databricks/jobs/job_task_map.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: `databricks/jobs/job_task_map.md`

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 14.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Lakeflow Jobs task map

```mermaid
flowchart TD
 E[environment_check] --> B1[bronze_sqlserver]

```

[Back to the Phase 14 lesson index](#phase-14-lesson-index)

## What your screen should look like now

- Every Phase 14 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

## Lesson 14.3 completion checklist

- [ ] `databricks/jobs/job\_definition.example.yml` was created by me, saved, located correctly, and inspected – [STATUS]
- [ ] `databricks/jobs/job\_task\_map.md` was created by me, saved, located correctly, and inspected – [STATUS]

## Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 14.4] (#phase-14-lesson-4) and recheck the root and branch.

<a id="phase-14-lesson-4"></a>

## Lesson 14.4 – Build and validate required objects

## What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

<a id="job-environmentcheck"></a>

### Databricks Job task 1 – `environment\_check`

```

Notebook: `databricks/notebooks/00_environment_check.py`
Depends on: No upstream task; this is the environment/start gate.
Inputs: Job parameters, upstream verified tables/files, and task outputs named in the task map.
Output: A validated table set, quality status, export, or demonstration result for the current Job run.
Retry policy: Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.
Timeout: Set a finite threshold large enough for the fixture but short enough to surface a stuck task.
Idempotency expectation: Repairing or rerunning the task for the same batch must not create unintended duplicates.

```

<a id="action-14-4-j1"></a>

## Action 14.4.J1 – Create and validate the `environment\_check` Lakeflow Job task

**\*\*Application:\*\***  
Databricks workspace in a web browser

**\*\*Window or panel:\*\***  
Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**\*\*Starting condition:\*\***  
The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**\*\*Current folder or location:\*\***  
The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

**\*\*What you are about to do:\*\***  
Create and validate the `environment\_check` Lakeflow Job task. This is one bounded construction or inspection task.

**\*\*Why this action comes now:\*\***  
It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**\*\*Exact physical actions:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name `environment\_check` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to `databricks/notebooks/00\_environment\_check.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select No upstream task; this is the environment/start gate..
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*Command or code:\*\***  
No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**\*\*Where to enter it:\*\***  
Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**\*\*What each part means:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name `environment\_check` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to `databricks/notebooks/00\_environment\_check.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select No upstream task; this is the environment/start gate..
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*What should happen:\*\***  
A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**\*\*Expected example:\*\***  
> Your exact values may differ. The expected result is the same \*type\* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**\*\*What may look different:\*\***  
Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**\*\*How to verify success:\*\***  
Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**\*\*Do not continue unless:\*\***  
You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

**\*\*Common mistake:\*\***  
Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**\*\*Exact recovery:\*\***  
Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**\*\*What you just accomplished:\*\***

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**\*\*How this connects to the project:\*\***

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#phase-14-lesson-index)

#### #### Run-history verification

1. Open the run from the **\*\*Start time\*\*** or matrix view.
2. Click ``environment_check``.
3. Record the run ID, task attempt, notebook path, parameters, start/end time, compute, and final state.
4. Open output and locate the entity/batch-specific validation summary.
5. If the task fails, copy the first meaningful exception and the deepest caused-by message, not only the red status.
6. Confirm dependent tasks are skipped when the failure is blocking.

#### #### Repair-run branch

- Open the failed run.
- Click **\*\*Repair run\*\***.
- Select the failed task and automatically dependent tasks shown by Databricks.
- Override parameters only when the correction requires it; record every override.
- Run the repair.
- Verify the repaired column/status in the matrix and inspect outputs again.
- Confirm tasks that already succeeded were not unnecessarily duplicated.

#### #### Common mistake

Selecting a similarly named notebook from a Drafts folder, omitting a parameter because a previous interactive run had a widget value, or using retries to hide a deterministic failure.

#### #### Interview-ready explanation

"I configured ``environment_check`` as an explicit Job node with declared dependencies, parameters, finite retry/timeout behavior, and output validation. I used repair runs for failed/dependent tasks and checked same-batch idempotency."

<a id="job-bronzeqlserver"></a>

### Databricks Job task 2 – ``bronze_sqlserver``

**\*\*Notebook:\*\*** ``databricks/notebooks/01_bronze_sqlserver.py``

**\*\*Depends on:\*\*** ``environment_check``

**\*\*Inputs:\*\*** Job parameters, upstream verified tables/files, and task outputs named in the task map.

**\*\*Output:\*\*** A validated table set, quality status, export, or demonstration result for the current Job run.

**\*\*Retry policy:\*\*** Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.

**\*\*Timeout:\*\*** Set a finite threshold large enough for the fixture but short enough to surface a stuck task.

**\*\*Idempotency expectation:\*\*** Repairing or rerunning the task for the same batch must not create unintended duplicates.

<a id="action-14-4-j2"></a>

## Action 14.4.J2 – Create and validate the ``bronze_sqlserver`` Lakeflow Job task

**\*\*Application:\*\***

Databricks workspace in a web browser

**\*\*Window or panel:\*\***

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**\*\*Starting condition:\*\***

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**\*\*Current folder or location:\*\***

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

**\*\*What you are about to do:\*\***

Create and validate the ``bronze_sqlserver`` Lakeflow Job task. This is one bounded construction or inspection task.

**\*\*Why this action comes now:\*\***

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**\*\*Exact physical actions:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name ``bronze_sqlserver`` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to ``databricks/notebooks/01_bronze_sqlserver.py`` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add ``batch_id``, ``catalog``, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select ``environment_check``.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.

12. PRESS: Run now only when all required dependencies and parameters are verified.  
 13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.  
 14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*Command or code:\*\***

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**\*\*Where to enter it:\*\***  
 Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**\*\*What each part means:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name ``bronze_sqlserver`` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to ``databricks/notebooks/01_bronze_sqlserver.py`` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add ``batch_id``, ``catalog``, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select ``environment_check``.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*What should happen:\*\***  
 A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**\*\*Expected example:\*\***

> Your exact values may differ. The expected result is the same *\*type\** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**\*\*What may look different:\*\***  
 Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**\*\*How to verify success:\*\***  
 Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**\*\*Do not continue unless:\*\***  
 You can point to the visible result and explain what it proves. Mark the action ``VERIFIED BY USER`` only after that check.

**\*\*Common mistake:\*\***  
 Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**\*\*Exact recovery:\*\***  
 Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**\*\*What you just accomplished:\*\***  
 You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**\*\*How this connects to the project:\*\***  
 The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

<a id="job-silvercustomers"></a>

### Databricks Job task 5 – `silver_customers``

**Notebook:** `databricks/notebooks/04_silver_customers.py``

**Depends on:** `bronze_sqlserver``

**Inputs:** Job parameters, upstream verified tables/files, and task outputs named in the task map.

**Output:** A validated table set, quality status, export, or demonstration result for the current Job run.

**Retry policy:** Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.

**Timeout:** Set a finite threshold large enough for the fixture but short enough to surface a stuck task.

**Idempotency expectation:** Repairing or rerunning the task for the same batch must not create unintended duplicates.

<a id="action-14-4-j5"></a>

## Action 14.4.J5 – Create and validate the `silver_customers`` Lakeflow Job task

**Application:**

Databricks workspace in a web browser

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

**What you are about to do:**

Create and validate the `silver_customers`` Lakeflow Job task. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. CLICK: In the Databricks left sidebar, select **Jobs & Pipelines**. A workspace may show **Workflows** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **Create Job** for the first task.
3. TYPE THIS: Enter task name `silver_customers`` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **Notebook** as the task type.
5. CLICK: Browse to `databricks/notebooks/04_silver_customers.py`` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch_id``, `catalog``, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `bronze_sqlserver``.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**\*\*What each part means:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name `silver\_customers` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to `databricks/notebooks/04\_silver\_customers.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `bronze\_sqlserver`.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*What should happen:\*\***

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**\*\*Expected example:\*\***

> Your exact values may differ. The expected result is the same *\*type\** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**\*\*What may look different:\*\***

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**\*\*How to verify success:\*\***

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**\*\*Do not continue unless:\*\***

You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

**\*\*Common mistake:\*\***

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**\*\*Exact recovery:\*\***

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**\*\*What you just accomplished:\*\***

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**\*\*How this connects to the project:\*\***

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#phase-14-lesson-index)

#### #### Run-history verification

1. Open the run from the **\*\*Start time\*\*** or matrix view.
2. Click `silver\_customers`.
3. Record the run ID, task attempt, notebook path, parameters, start/end time, compute, and final state.
4. Open output and locate the entity/batch-specific validation summary.
5. If the task fails, copy the first meaningful exception and the deepest caused-by message, not only the red status.
6. Confirm dependent tasks are skipped when the failure is blocking.

#### #### Repair-run branch

- Open the failed run.
- Click **\*\*Repair run\*\***.
- Select the failed task and automatically dependent tasks shown by Databricks.
- Override parameters only when the correction requires it; record every override.
- Run the repair.
- Verify the repaired column/status in the matrix and inspect outputs again.
- Confirm tasks that already succeeded were not unnecessarily duplicated.

#### #### Common mistake

Selecting a similarly named notebook from a Drafts folder, omitting a parameter because a previous interactive run had a widget value, or using retries to hide a deterministic failure.

#### #### Interview-ready explanation

"I configured `silver\_customers` as an explicit Job node with declared dependencies, parameters, finite retry/timeout behavior, and output validation. I used repair runs for failed/dependent tasks and checked same-batch idempotency."

<a id="job-silverproducts"></a>

### Databricks Job task 6 – `silver\_products`

**\*\*Notebook:\*\*** `databricks/notebooks/05\_silver\_products.py`

**\*\*Depends on:\*\*** `bronze\_sqlserver`, `bronze\_files`

```

Inputs: Job parameters, upstream verified tables/files, and task outputs named in the task map.
Output: A validated table set, quality status, export, or demonstration result for the current Job run.
Retry policy: Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.
Timeout: Set a finite threshold large enough for the fixture but short enough to surface a stuck task.
Idempotency expectation: Repairing or rerunning the task for the same batch must not create unintended duplicates.

Action 14.4.J6 – Create and validate the `silver_products` Lakeflow Job task

Application:
Databricks workspace in a web browser

Window or panel:
Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:
The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:
The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:
Create and validate the `silver_products` Lakeflow Job task. This is one bounded construction or inspection task.

Why this action comes now:
It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:
1. CLICK: In the Databricks left sidebar, select **Jobs & Pipelines**. A workspace may show **Workflows** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **Create Job** for the first task.
3. TYPE THIS: Enter task name `silver_products` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **Notebook** as the task type.
5. CLICK: Browse to `databricks/notebooks/05_silver_products.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `bronze_sqlserver`, `bronze_files`.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

Command or code:
No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:
Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:
1. CLICK: In the Databricks left sidebar, select **Jobs & Pipelines**. A workspace may show **Workflows** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **Create Job** for the first task.
3. TYPE THIS: Enter task name `silver_products` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **Notebook** as the task type.
5. CLICK: Browse to `databricks/notebooks/05_silver_products.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `bronze_sqlserver`, `bronze_files`.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

What should happen:
A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:
> Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:
Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:
Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

```

**\*\*Do not continue unless:\*\***  
You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

"I configured ``silver_digital`` as an explicit Job node with declared dependencies, parameters, finite retry/timeout behavior, and output validation. I used repair runs for failed/dependent tasks and checked same-batch idempotency."

<a id="job-golddimensions"></a>  
 #### Databricks Job task 9 – ``gold_dimensions``

**\*\*Notebook:\*\*** ``databricks/notebooks/08_gold_dimensions.py``  
**\*\*Depends on:\*\*** ``silver_customers``, ``silver_products``, ``silver_digital``, ``bronze_files``  
**\*\*Inputs:\*\*** Job parameters, upstream verified tables/files, and task outputs named in the task map.  
**\*\*Output:\*\*** A validated table set, quality status, export, or demonstration result for the current Job run.  
**\*\*Retry policy:\*\*** Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.  
**\*\*Timeout:\*\*** Set a finite threshold large enough for the fixture but short enough to surface a stuck task.  
**\*\*Idempotency expectation:\*\*** Repairing or rerunning the task for the same batch must not create unintended duplicates.

<a id="action-14-4-j9"></a>  
 ## Action 14.4.J9 – Create and validate the ``gold_dimensions`` Lakeflow Job task

**\*\*Application:\*\***  
 Databricks workspace in a web browser

**\*\*Window or panel:\*\***

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**\*\*Starting condition:\*\***

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**\*\*Current folder or location:\*\***

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

**\*\*What you are about to do:\*\***

Create and validate the `gold\_dimensions` Lakeflow Job task. This is one bounded construction or inspection task.

**\*\*Why this action comes now:\*\***

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**\*\*Exact physical actions:\*\***

1. CLICK: In the Databricks left sidebar, select **Jobs & Pipelines**. A workspace may show **Workflows** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **Create Job** for the first task.
3. TYPE THIS: Enter task name `gold\_dimensions` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **Notebook** as the task type.
5. CLICK: Browse to `databricks/notebooks/08\_gold\_dimensions.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `silver\_customers`, `silver\_products`, `silver\_digital`, `bronze\_files`.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*Command or code:\*\***

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**\*\*Where to enter it:\*\***

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**\*\*What each part means:\*\***

1. CLICK: In the Databricks left sidebar, select **Jobs & Pipelines**. A workspace may show **Workflows** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **Create Job** for the first task.
3. TYPE THIS: Enter task name `gold\_dimensions` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **Notebook** as the task type.
5. CLICK: Browse to `databricks/notebooks/08\_gold\_dimensions.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `silver\_customers`, `silver\_products`, `silver\_digital`, `bronze\_files`.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*What should happen:\*\***

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**\*\*Expected example:\*\***

> Your exact values may differ. The expected result is the same *\*type\** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**\*\*What may look different:\*\***

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**\*\*How to verify success:\*\***

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**\*\*Do not continue unless:\*\***

You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

**\*\*Common mistake:\*\***

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**\*\*Exact recovery:\*\***

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**\*\*What you just accomplished:\*\***

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**\*\*How this connects to the project:\*\***

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#phase-14-lesson-index)

#### #### Run-history verification

1. Open the run from the **\*\*Start time\*\*** or matrix view.
2. Click ``gold_dimensions``.
3. Record the run ID, task attempt, notebook path, parameters, start/end time, compute, and final state.
4. Open output and locate the entity/batch-specific validation summary.
5. If the task fails, copy the first meaningful exception and the deepest caused-by message, not only the red status.
6. Confirm dependent tasks are skipped when the failure is blocking.

#### #### Repair-run branch

- Open the failed run.
- Click **\*\*Repair run\*\***.
- Select the failed task and automatically dependent tasks shown by Databricks.
- Override parameters only when the correction requires it; record every override.
- Run the repair.
- Verify the repaired column/status in the matrix and inspect outputs again.
- Confirm tasks that already succeeded were not unnecessarily duplicated.

#### #### Common mistake

Selecting a similarly named notebook from a Drafts folder, omitting a parameter because a previous interactive run had a widget value, or using retries to hide a deterministic failure.

#### #### Interview-ready explanation

"I configured ``gold_dimensions`` as an explicit Job node with declared dependencies, parameters, finite retry/timeout behavior, and output validation. I used repair runs for failed/dependent tasks and checked same-batch idempotency."

<a id="job-goldfacts"></a>

## Databricks Job task 10 – ``gold_facts``

**\*\*Notebook:\*\*** ``databricks/notebooks/09_gold_facts.py``  
**\*\*Depends on:\*\*** ``gold_dimensions``, ``silver_sales``, ``silver_digital``  
**\*\*Inputs:\*\*** Job parameters, upstream verified tables/files, and task outputs named in the task map.  
**\*\*Output:\*\*** A validated table set, quality status, export, or demonstration result for the current Job run.  
**\*\*Retry policy:\*\*** Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.  
**\*\*Timeout:\*\*** Set a finite threshold large enough for the fixture but short enough to surface a stuck task.  
**\*\*Idempotency expectation:\*\*** Repairing or rerunning the task for the same batch must not create unintended duplicates.

<a id="action-14-4-j10"></a>

## Action 14.4.J10 – Create and validate the ``gold_facts`` Lakeflow Job task

**\*\*Application:\*\***

Databricks workspace in a web browser

**\*\*Window or panel:\*\***

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**\*\*Starting condition:\*\***

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**\*\*Current folder or location:\*\***

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

**\*\*What you are about to do:\*\***

Create and validate the ``gold_facts`` Lakeflow Job task. This is one bounded construction or inspection task.

**\*\*Why this action comes now:\*\***

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**\*\*Exact physical actions:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name ``gold_facts`` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to ``databricks/notebooks/09_gold_facts.py`` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add ``batch_id``, ``catalog``, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select ``gold_dimensions``, ``silver_sales``, ``silver_digital``.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*Command or code:\*\***

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**\*\*Where to enter it:\*\***

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**\*\*What each part means:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name ``gold_facts`` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to ``databricks/notebooks/09_gold_facts.py`` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add ``batch_id``, ``catalog``, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select ``gold_dimensions``, ``silver_sales``, ``silver_digital``.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*What should happen:\*\***

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**\*\*Expected example:\*\***

> Your exact values may differ. The expected result is the same *\*type\** of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**\*\*What may look different:\*\***

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**\*\*How to verify success:\*\***

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**\*\*Do not continue unless:\*\***

You can point to the visible result and explain what it proves. Mark the action ``VERIFIED BY USER`` only after that check.

**\*\*Common mistake:\*\***

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**\*\*Exact recovery:\*\***

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**\*\*What you just accomplished:\*\***

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**\*\*How this connects to the project:\*\***

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

"I configured `publish\_gold` as an explicit Job node with declared dependencies, parameters, finite retry/timeout behavior, and output validation. I used repair runs for failed/dependent tasks and checked same-batch idempotency."

<a id="job-demoqueries"></a>

### Databricks Job task 13 – `demo\_queries`

**\*\*Notebook:\*\*** `databricks/notebooks/12\_demo\_queries.py`

**\*\*Depends on:\*\*** `publish\_gold`

**\*\*Inputs:\*\*** Job parameters, upstream verified tables/files, and task outputs named in the task map.

**\*\*Output:\*\*** A validated table set, quality status, export, or demonstration result for the current Job run.

**\*\*Retry policy:\*\*** Retry only transient failures; deterministic data-quality failures require diagnosis rather than repeated compute cost.

**\*\*Timeout:\*\*** Set a finite threshold large enough for the fixture but short enough to surface a stuck task.

**\*\*Idempotency expectation:\*\*** Repairing or rerunning the task for the same batch must not create unintended duplicates.

<a id="action-14-4-j13"></a>

## Action 14.4.J13 – Create and validate the `demo\_queries` Lakeflow Job task

**\*\*Application:\*\***

Databricks workspace in a web browser

**\*\*Window or panel:\*\***

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**\*\*Starting condition:\*\***

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**\*\*Current folder or location:\*\***

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

**\*\*What you are about to do:\*\***

Create and validate the `demo\_queries` Lakeflow Job task. This is one bounded construction or inspection task.

**\*\*Why this action comes now:\*\***

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**\*\*Exact physical actions:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.
3. TYPE THIS: Enter task name `demo\_queries` exactly; avoid spaces when the project map uses underscores.
4. CLICK: Choose **\*\*Notebook\*\*** as the task type.
5. CLICK: Browse to `databricks/notebooks/12\_demo\_queries.py` in the verified workspace/Git folder.
6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.
7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.
8. CLICK: Under dependencies, select `publish\_gold`.
9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.
10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.
11. CLICK: Save task.
12. PRESS: Run now only when all required dependencies and parameters are verified.
13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.
14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**\*\*Command or code:\*\***

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**\*\*Where to enter it:\*\***

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**\*\*What each part means:\*\***

1. CLICK: In the Databricks left sidebar, select **\*\*Jobs & Pipelines\*\***. A workspace may show **\*\*Workflows\*\*** in an alternate interface.
2. CLICK: Open the Northstar Retail Job or select **\*\*Create Job\*\*** for the first task.

3. TYPE THIS: Enter task name `demo\_queries` exactly; avoid spaces when the project map uses underscores.

4. CLICK: Choose **Notebook** as the task type.

5. CLICK: Browse to `databricks/notebooks/12\_demo\_queries.py` in the verified workspace/Git folder.

6. CLICK: Select the compute option available to your workspace and appropriate to the notebook.

7. TYPE THIS: Add `batch\_id`, `catalog`, and other parameters exactly as the notebook reads them.

8. CLICK: Under dependencies, select `publish\_gold`.

9. CLICK: Open advanced settings and set retries/timeouts from the documented policy; do not choose unlimited retries.

10. CLICK: Add failure notification only to a channel/address you are authorized to use, or record that notifications are not configured.

11. CLICK: Save task.

12. PRESS: Run now only when all required dependencies and parameters are verified.

13. LOOK FOR: Open task output and confirm the exact notebook, parameter values, compute, and result.

14. DO NOT CONTINUE UNTIL: The task's output and downstream dependency behavior match the Job map.

**What should happen:**

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**Expected example:**

> Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**What may look different:**

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**How to verify success:**

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**Do not continue unless:**

You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 14 lesson index](#phase-14-lesson-index)

#### Run-history verification

1. Open the run from the **Start time** or matrix view.
2. Click `demo\_queries`.
3. Record the run ID, task attempt, notebook path, parameters, start/end time, compute, and final state.
4. Open output and locate the entity/batch-specific validation summary.
5. If the task fails, copy the first meaningful exception and the deepest caused-by message, not only the red status.
6. Confirm dependent tasks are skipped when the failure is blocking.

#### Repair-run branch

- Open the failed run.
- Click **Repair run**.
- Select the failed task and automatically dependent tasks shown by Databricks.
- Override parameters only when the correction requires it; record every override.
- Run the repair.
- Verify the repaired column/status in the matrix and inspect outputs again.
- Confirm tasks that already succeeded were not unnecessarily duplicated.

#### Common mistake

Selecting a similarly named notebook from a Drafts folder, omitting a parameter because a previous interactive run had a widget value, or using retries to hide a deterministic failure.

#### Interview-ready explanation

"I configured `demo\_queries` as an explicit Job node with declared dependencies, parameters, finite retry/timeout behavior, and output validation. I used repair runs for failed/dependent tasks and checked same-batch idempotency."

## What your screen should look like now

- The new Phase 14 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

## ## Lesson 14.4 completion checklist

- [ ] Every required object was built separately – [STATUS]
- [ ] Every object has a declared responsibility/grain – [STATUS]
- [ ] Inputs and outputs were inspected – [STATUS]
- [ ] A rerun or alternate-result branch was tested where applicable – [STATUS]
- [ ] Counts, keys, measures, relationships, or settings were independently validated – [STATUS]
- [ ] I can explain one failure and its safest recovery – [STATUS]

## ## Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 14.5](#phase-14-lesson-5).

<a id="phase-14-lesson-5"></a>

## ## Lesson 14.5 – Verify, troubleshoot, commit, teach back, and stop safely

### ## What your screen should look like before starting

The Phase 14 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

### ## Design decision – Verification before automation

**\*\*Question:\*\***

Should the phase prioritize a visible manual verification or jump directly to automation?

**\*\*Options considered:\*\***

- Manual verification first, then automation.
- Automation without a known-good baseline.
- Manual operation forever.

**\*\*Beginner path selected:\*\***

Establish one verified manual baseline and then automate repeatable checks.

**\*\*Why this path was selected:\*\***

A known-good example makes failures interpretable and prevents automation from hiding a wrong assumption.

**\*\*Tradeoff:\*\***

The first run takes longer.

**\*\*What a company might do instead:\*\***

Teams often pair infrastructure as code and automated tests with controlled bootstrap and acceptance procedures.

**\*\*How to explain this in an interview:\*\***

I established a verified baseline, then encoded the same contract in tests and orchestration so automation preserved meaning rather than just speed.

### ## If you see Result A

The Job DAG completes and the run history shows successful dependent tasks. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

### ## If you see Result B

A task fails or is skipped; repair targets only the failed/downstream tasks after the cause is fixed. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

### ## If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

### ## Phase-specific verification gate

- [ ] Required files/objects exist in the exact location.
- [ ] I personally created or configured them.
- [ ] I ran the phase commands in the documented context.
- [ ] I inspected the output rather than relying on a green icon alone.
- [ ] Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.
- [ ] Same-batch/rerun behavior is known where applicable.
- [ ] A controlled failure or realistic alternate-result branch was tested safely where applicable.
- [ ] No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.
- [ ] Actual verified result: `[ENTER VERIFIED RESULT]`.

### ## Point-of-failure troubleshooting record

**\*\*Exact or representative error message:\*\***

```
`[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]`

What it means in plain language:
`[WRITE YOUR INTERPRETATION]`

Most likely cause:
`[WRITE ONE TESTABLE HYPOTHESIS]`

What not to do:
Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:
`[ENTER THE SMALLEST OBSERVATIONAL CHECK]`

How to read the diagnostic result:
`[RESULT A MEANS... / RESULT B MEANS...]`

Safest fix:
`[ENTER THE NARROW FIX]`

Alternative fix when applicable:
`[ENTER OR N/A]`

How to verify the fix:
`[ENTER THE INDEPENDENT RECHECK]`

How to return to the main tutorial:
Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Databricks Jobs & Pipelines, notebook task pages, run history, and notifications settings.
Window/panel: Show Job DAG, run matrix, failed task, skipped dependency, and repair-run success.
Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.
Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.
Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.
Recommended filename: `docs/images/phase14_create-and-operate-a-multi-task-databricks-job_verified.png`.
Recommended repository folder: `docs/images/`.
README placement: The section describing Phase 14's verified result; do not use the image before the result is actually verified.
What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

`[ADD YOUR VERIFIED SCREENSHOT HERE]`

Git checkpoint after the verified Phase 14 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 14.5.G1 – Verify the repository root before Git operations

Application:
Windows PowerShell or the VS Code PowerShell terminal

Window or panel:
VS Code integrated PowerShell terminal

Starting condition:
The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:
The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:
Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:
The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches `The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.` or the more specific location stated below.
```

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.  
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.  
5. PRESS: Press **\*\*Enter\*\*** for a one-line terminal command, **\*\*F5/Execute\*\*** for the named database editor, or the notebook cell Run control as stated.  
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.  
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**\*\*Command or code (PowerShell):\*\***

```
```powershell  
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 14.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.

- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 14.5.G4 — Inspect the unstaged diff for databricks/jobs/job_definition.example.yml

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "databricks/jobs/job_definition.example.yml"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "databricks/jobs/job_definition.example.yml"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/jobs/job_definition.example.yml"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.5.G5 — Stage only the reviewed file `databricks/jobs/job_definition.example.yml`

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.

2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "databricks/jobs/job_definition.example.yml"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "databricks/jobs/job_definition.example.yml"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"databricks/jobs/job_definition.example.yml"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 14.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.5.G7 — Create the Phase 14 commit

Application:

Databricks workspace in a web browser

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: orchestrate northstar lakehouse job"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: orchestrate northstar lakehouse job"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: orchestrate northstar lakehouse job"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Action 14.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 14 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: orchestrate northstar lakehouse job` and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 14.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 14 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 14 created the verified boundary described by **Create and operate a multi-task Databricks Job**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

Mini quiz

1. Multiple choice: Why does Phase 14 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
4. What command would you use first to confirm the PowerShell current folder before a repository command?

5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** PLANNED, CREATED BY USER, and RUN BY USER describe earlier states; only inspected evidence supports verification.

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.

- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 14.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 15 exports only verified Gold results and loads them into the local warehouse.

Phase 14 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 15 — Publish Gold data into the SQL Server dimensional warehouse

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: A validated SQL Server dimensional warehouse.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 16 imports trusted tables, builds relationships, and defines DAX measures.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 15 lesson index

1. [Lesson 15.1 — Understand the phase and starting screen](#)
2. [Lesson 15.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 15.3 — Create and understand the phase files](#)
4. [Lesson 15.4 — Build and validate required objects](#)
5. [Lesson 15.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 15.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Databricks, File Explorer, PowerShell, SSMS, and Python.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 15 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 14 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 15 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Databricks, File Explorer, PowerShell, SSMS, and Python. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 15 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 15 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 15 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 15.1 completion checklist

☐

I read why Phase 15 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 15.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 15 lesson index](#)

Lesson 15.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 15 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A local SQL Server warehouse named NorthstarRetail_DW with dw, stg, audit, and semantic schemas, dimension/fact DDL, unknown rows, constraints/indexes, staging and transactional publication, load audit/reconciliation, semantic views, and exact SSMS inspection steps. Track A uses Gold export/download; Track B direct publication remains optional.

2. Why it matters

Gold Delta is business-ready, but a SQL Server serving mirror teaches warehouse DDL, transactional stage-and-publish, relational constraints/indexes, local Power BI connectivity, and cross-platform reconciliation. The manual download preserves the honest localhost boundary.

3. Words to know

Term	Plain-language definition
Serving warehouse	Curated database optimized for analyst/BI consumption.
Staging schema	Temporary load tables before target publish.
Transactional publication	Stage/validate/delete-merge/insert/audit commit as one unit.
Full development reload	Replace target scope safely in disposable development.
Incremental publication	Apply new/changed rows while preserving history.
Audit table	Records batch process status/timing/errors.
Reconciliation table	Stores source/target values/differences/status.
Clustered/nonclustered index	SQL Server physical/access structures; design depends on workload.
Primary/foreign key	Relational integrity constraints in serving layer.
Semantic view	Stable SQL view exposing business-friendly columns.
Parquet export	Columnar Gold files downloaded from volume.
Direct publication	Track B write over reachable network/JDBC/connector, requiring security/network support.
Rollback	Transaction reverts target changes after failure.

4. What must already be completed

Job quality gate passes; all Gold tables exist; publish notebook exports manifest/path; local SQL Server/SSMS/ODBC works; downloaded files are in one known folder; disk space available.

5. Applications to open

Application	How to open it	Why it is open
Databricks Job/notebook 11	Workspace.	Export Gold after quality gate.
Databricks volume browser	Gold export folder.	Download exact batch export/manifest.
Windows PowerShell	Repository root with .venv active.	Create DB through SSMS then run local loader.

Application	How to open it	Why it is open
SSMS	Local server.	Run warehouse DDL, inspect/stage/validate.
VS Code	Warehouse DDL, loader, validation, semantic views.	Review transaction logic before execution.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
SELECT @@SERVERNAME AS server_name, SUSER_SNAME() AS login_name, DB_NAME() AS database_name;	Verifies server/login/context.	ERP and DW have similar names; context mistakes are dangerous.
-- Execute the entire 01_create_warehouse.sql file.	Creates DW schemas/tables/constraints/indexes/ unknown rows.	Loader needs target contract.
-- Execute 02_create_staging_tables.sql, then 03_semantic_views.sql.	Creates staging mirrors and business-friendly views.	Publication isolates incoming files and Power BI can use stable semantic access.
python -m scripts.loading.load_gold_to_sqlserver --input-dir "C: \\Users\\User\\Downloads\\gold_exports\\EXT- YYYYMMDDTHMMSSZ" --mode full-dev	Stages and transactionally publishes all Gold tables into the local DW.	This is Track A's controlled local serving handoff.
-- Execute sql/sqlserver/validation/02_valid- ate_warehouse.sql	Checks duplicate fact grain, dimension RI, SCD current rows, revenue identity, audit/reconcili- ation.	Loader success does not prove model correct- ness.
SELECT TOP (20) * FROM semant- ic.vw_executive_daily_kpi ORDER BY full_date DESC;	Queries serving semantic view.	Confirms views compile and aggregate loaded warehouse.

Safe full-dev order

Stage every table first. Validate stage counts/schema. Delete fact tables before dimensions to satisfy foreign keys. Insert dimensions in dependency order, then facts. Recreate/retain unknown rows consistently. Record audit/reconciliation and commit once. On exception, roll back.

Incremental tradeoff

An incremental warehouse publish must MERGE Type 1 dimensions, append/expire SCD2 versions correctly, upsert facts by immutable grain, handle deletes/corrections, and reconcile the batch. Full-dev is simpler and transparent for small learning data; it is not a production claim.

MY TASK

Review/fix the local loader for fact-before-dimension deletion and explicit target columns, publish one validated batch, prove rollback with a safe staged failure, reconcile Gold to DW, and verify a same-batch reload.

STARTER SKELETON

```
# TODO(USER): safe full-dev publication outline
with engine.begin() as connection:
    stage_all_exports(connection, input_dir)
    validate_stage_counts(connection, manifest)
    for fact in reversed(FACT_TABLES):
        connection.execute(text(f"DELETE FROM dw.{fact}"))
    for dimension in reversed(DIMENSION_TABLES):
        connection.execute(text(f"DELETE FROM dw.{dimension} WHERE {dimension_key(dimension)} <> 0"))
    for dimension in DIMENSION_TABLES:
        insert_explicit_columns(connection, dimension)
    for fact in FACT_TABLES:
        insert_explicit_columns(connection, fact)
    record_reconciliation(connection, batch_id)
# TODO(USER): test a forced error rolls back target counts.
```

Acceptance criteria: Warehouse objects exist; publication is transactional and FK-safe; all Gold/SQL Server counts/amounts reconcile; invalid staged run rolls back; same-batch full-dev reload reproduces results; semantic views query successfully.

HINT 1 — CONCEPT

Delete child facts before parent dimensions; insert parents before children.

HINT 2 — PSEUDOCODE

Ask SQL Server `sys.columns` for insertable non-computed columns and use explicit lists.

HINT 3 — NEAR-COMPLETE PATTERN

Stage all tables and validate first; adapt skeleton inside one `engine.begin()` transaction.

13. Expected files or output

- NorthstarRetail_DW and four schemas.
- 9 dimensions, 6 facts, audit/reconciliation, staging tables, semantic views.
- SUCCESS audit/run artifact.
- Gold-to-DW reconciliation.
- Rollback and rerun evidence.

14. How to verify

- All target counts equal export manifest.
- No fact duplicates/orphan keys.
- SCD2 current/unknown rows valid.
- Revenue/profit match Gold.
- Forced failure leaves pre-run target state.
- Semantic view values match base query.
- ERP source unaffected.

15. Automated tests

- Warehouse validation SQL.
- Gold-to-DW count/amount checks.
- Transaction rollback test.
- Same-batch reproducibility.
- Constraint/index inspection.
- Semantic view query and KPI validation.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
FK delete conflict	Dimensions deleted before facts.	Read constraint/table error; inspect deletion order.	Delete child facts first inside transaction.	Reload succeeds.
Computed column insert error	SELECT * includes computed/non-insertable target column.	Inspect <code>sys.columns.is_computed</code> and stage schema.	Use explicit insertable column list.	fact_inventory loads.
Missing Gold export	Fact TODO incomplete or download structure lost.	List input directory and Databricks manifest.	Complete Gold, rerun gated publish, preserve folders.	All 15 exports found.
Partial warehouse changes	Operations not in one transaction or DDL auto-commit boundary.	Compare audit/status/counts after forced failure.	Stage/validate then data DML in one transaction; avoid DDL in load transaction.	Rollback restores state.
Power BI later sees no tables	Wrong database/schema/permission or import selection.	SSMS context and view/table queries.	Use NorthstarRetail_DW and read-only rights on dw/semantic.	SQL query succeeds.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why stage all exports before deleting targets?
2. Why delete facts before dimensions?
3. What does a transaction protect here?
4. What additional controls does Track B require?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What is the SQL Server warehouse database name?
2. Which columns should be excluded from explicit insert lists?
3. Why is full-dev acceptable here but not automatically production-ready?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture Object Explorer warehouse schemas, SUCCESS audit row, reconciliation results, and semantic view output with batch ID. Do not show passwords/server secrets.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: publish validated gold to sql server warehouse
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Warehouse DDL/staging/views created — [STATUS]

☐

Loader reviewed/fixed — [STATUS]

☐

Gold export complete — [STATUS]

☐

Transactional load succeeded — [STATUS]

☐

Gold-to-DW reconciliation passed — [STATUS]

☐

Rollback tested — [STATUS]

☐

Same-batch reload stable — [STATUS]

☐

SSMS inspection captured — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-15. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-15.

Next phase: Phase 16 creates the Power BI semantic model and validates DAX measures against the serving warehouse.

Required action cards

Action 15.2.1 — Confirm 11_publish_gold ran only after quality PASS and printed /gold_exports/<batch_id> plus row manifest

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Confirm 11_publish_gold ran only after quality PASS and printed /gold_exports/<batch_id> plus row manifest. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Confirm 11_publish_gold ran only after quality PASS and printed /gold_exports/<batch_id> plus row manifest.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Confirm `11_publish_gold` ran only after quality PASS and printed `/gold_exports/<batch_id>` plus row manifest.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Action 15.2.2 — Download the entire Gold export folder, preserving each `table.parquet` directory/file structure and ``_manifests`

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Download the entire Gold export folder, preserving each table.parquet directory/file structure and _manifest. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Download the entire Gold export folder, preserving each table.parquet directory/file structure and _manifest. Record local download path/checksum where practical.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

Download the entire Gold export folder, preserving each table.parquet directory/file structure and _manifest. Record local download path/checksum where practical.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Action 15.2.3 — Open SSMS and reconnect to verified local server. Run context query.

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Open SSMS and reconnect to verified local server. Run context query. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open SSMS and reconnect to verified local server. Run context query.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

Open SSMS and reconnect to verified local server. Run context query.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Action 15.2.4 — Open/execute sql/sqlserver/warehouse/01_create_warehouse.sql, then 02_create_staging_tables.sql, then `03_

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Open/execute sql/sqlserver/warehouse/01_create_warehouse.sql, then 02_create_staging_tables.sql, then `03_. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open/execute `sql/sqlserver/warehouse/01_create_warehouse.sql`, then `02_create_staging_tables.sql`, then `03_semantic_views.sql`. Read messages and object inventory.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 4****Action**

Open/execute `sql/sqlserver/warehouse/01_create_warehouse.sql`, then `02_create_staging_tables.sql`, then `03_semantic_views.sql`. Read messages and object inventory.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Action 15.2.6 — Before loading, open scripts/loading/load_gold_to_sqlserver.py. Confirm it stages all exports, deletes facts

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Before loading, open scripts/loading/load_gold_to_sqlserver.py. Confirm it stages all exports, deletes facts. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Before loading, open scripts/loading/load_gold_to_sqlserver.py. Confirm it stages all exports, deletes facts before dimensions for a full development reload, preserves transaction, uses explicit insertable columns, and writes audit status. If your current version differs, complete/fix the TODO before running.

4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 6****Action**

Before loading, open `scripts/loading/load_gold_to_sqlserver.py`. Confirm it stages all exports, deletes facts before dimensions for a full development reload, preserves transaction, uses explicit insertable columns, and writes audit status. If your current version differs, complete/fix the TODO before running.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Action 15.2.7 — Run local loader with exact download folder and full-dev only in this disposable learning warehouse. Do not

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run local loader with exact download folder and full-dev only in this disposable learning warehouse. Do not . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Run local loader with exact download folder and full-dev only in this disposable learning warehouse. Do not point it at ERP source.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 7

Action

Run local loader with exact download folder and full-dev only in this disposable learning warehouse. Do not point it at ERP source.

Before continuing

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Action 15.2.C1 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT @@SERVERNAME AS server_name, SUSER_SNAME() AS login_name, DB_NAME() AS database_name;
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT @@SERVERNAME AS server_name, SUSER_SNAME() AS login_name, DB_NAME() AS database_name; — SELECT requests data without changing it unless combined with a modifying statement; SERVERNAME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; server_name is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SUSER_SNAME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; login_name is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; DB_NAME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.2.C2 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
-- Execute the entire 01_create_warehouse.sql file.
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `-- Execute the entire 01_create_warehouse.sql file.` is a comment for a human reader; it normally does not change data or execute business logic.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.2.C3 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
-- Execute 02_create_staging_tables.sql, then 03_semantic_views.sql.
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** -- Execute 02_create_staging_tables.sql, then 03_semantic_views.sql. is a comment for a human reader; it normally does not change data or execute business logic.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use

git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.2.C4 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.loading.load_gold_to_sqlserver --input-dir "C:\Users\User\Downloads\gold_exports\EXT-YYYYMMDDTHHMMSSZ" --mode full-dev
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m scripts.loading.load_gold_to_sqlserver --input-dir "C:\Users\User\Downloads\gold_exports\EXT-YYYYMMDDTHHMMSSZ" --mode full-dev` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.loading.load_gold_to_sqlserver` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--input` is a command option or flag; its exact behavior is defined beside the command; `-dir` is a command option or flag; its exact behavior is defined beside the command; `"C:\Users\User\Downloads\gold_exports\EXT-YYYYMMDDTHHMMSSZ"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `--mode` is a command option or flag; its exact behavior is defined beside the command; `full-dev` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

Action 15.2.C6 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT TOP (20) * FROM semantic.vw_executive_daily_kpi ORDER BY full_date DESC;
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT TOP (20) * FROM semantic.vw_executive_daily_kpi ORDER BY full_date DESC;` — `SELECT` requests data without changing it unless combined with a modifying statement; `TOP` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `20` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `*` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `semantic.vw_executive_daily_kpi` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ORDER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DESC` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 15.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 15 starting-screen checklist and re-verify the active context.

Lesson 15.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 15 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — scripts/

Exact folder name: scripts

Exact parent: repository root

Why it is needed now: Phase 15 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: scripts.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 15.D1.1 — Create the folder scripts

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\scripts" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\scripts" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/

Exact folder name: `sql`

Exact parent: `repository root`

Why it is needed now: Phase 15 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: sql.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 15.D2.1 — Create the folder sql

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\sql" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run Test-Path ".\sql" -PathType Container.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — scripts/loading/

Exact folder name: loading

Exact parent: scripts

Why it is needed now: Phase 15 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path scripts one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: loading.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 15.D3.1 — Create the folder scripts/loading

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 15.D6.1 — Create the folder sql/sqlserver/warehouse

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql\sqlserver\warehouse" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\sql\sqlserver\warehouse" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\warehouse"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql\sqlserver\warehouse" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\sqlserver\warehouse" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\sqlserver\warehouse" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — `sql/sqlserver/warehouse/01_create_warehouse.sql`

Exact filename: `01_create_warehouse.sql`

Filename extension: `.sql`. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `sql/sqlserver/warehouse` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 15.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `sql/sqlserver/warehouse` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `01_create_warehouse.sql`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `01_create_warehouse.sql` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 15.F1.1 — Create the file `sql/sqlserver/warehouse/01_create_warehouse.sql` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\warehouse\01_create_warehouse.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\warehouse\01_create_warehouse.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\warehouse\01_create_warehouse.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\sqlserver\warehouse\01_create_warehouse.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/warehouse/01_create_warehouse.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/warehouse`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/warehouse/01_create_warehouse.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\warehouse\01_create_warehouse.sql"` and require `True`.
4. Run `git status --short -- "sql/sqlserver/warehouse/01_create_warehouse.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/warehouse/01_create_warehouse.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/warehouse/01_create_warehouse.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 15.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

-- Dialect: SQL Server / T-SQL
-- Purpose: create the local serving warehouse NorthstarRetail_DW.
-- Run in: SSMS connected to your local SQL Server instance.
-- Safety: creates missing objects; it does not drop populated tables.

Line-by-line explanation

- **Line 1:** -- Dialect: SQL Server / T-SQL is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** -- Purpose: create the local serving warehouse NorthstarRetail_DW. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 3:** -- Run in: SSMS connected to your local SQL Server instance. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 4:** -- Safety: creates missing objects; it does not drop populated tables. is a comment for a human reader; it normally does not change data or execute business logic.
