Verification query

Action 4.4.S10.V — Verify metadata and row count for erp.payments

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.payments;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.payments;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.payments` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.

- **If the object matches exactly and was created by your verified earlier run:** Record VERIFIED BY USER and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.payments`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_payments_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.payments` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 11 — `erp.shipments`

Real-world object: shipments in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per shipment identifier. Verify that every column and example row describes that same unit.

Primary key: `shipment_id`

Foreign keys: `order_id` → `orders.order_id`; `shipping_address_id` → `addresses.address_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>shipment_id</code>	BIGINT	No	Yes	—	Shipment identifier	9300001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
<code>order_id</code>	BIGINT	No	No	<code>orders.order_id</code>	Shipped order	9000001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
<code>shipping_address_id</code>	INT	Yes	No	<code>addresses.address_id</code>	Destination address	500001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Nullable because the source can legitimately omit it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
carrier_code	VARCHAR(30)	No	No	—	Fictional carrier code	NORTHPARCEL	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
tracking_number	VARCHAR(80)	No	No	—	Synthetic tracking number	NP00000001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
ship_timestamp	DATETIME2	Yes	No	—	Shipment departure time	2026-01-05T10:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Nullable because the source can legitimately omit it
promised_delivery_date	DATE	Yes	No	—	Customer promise date	2026-01-08	a calendar date with no time-of-day component. Nullable because the source can legitimately omit it
delivery_timestamp	DATETIME2	Yes	No	—	Actual delivery time	2026-01-07T15:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Nullable because the source can legitimately omit it
shipment_status	VARCHAR(30)	No	No	—	Shipment status	DELIVERED	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
shipping_cost	DECIMAL(12,2)	No	No	—	Internal shipping cost	7.25	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
created_at	DATETIME2	No	No	—	Source creation timestamp	2026-01-05T10:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	DATETIME2	No	No	—	Source update timestamp	2026-01-07T15:00:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- shipment_id = 30000001
- order_id = 9000002
- carrier = National Ground
- tracking_number = NST9000002665
- ship_date = 2024-02-12
- promised_delivery_date = 2024-02-16
- actual_delivery_date = 2024-02-13
- shipment_status = DELIVERED
- shipping_cost = 7.99
- created_at = 2024-02-12T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S11 — Create and inspect erp.shipments

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect erp.shipments. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/sqlserver/source/02_create_erp_tables.sql in VS Code beside the database editor.
4. TYPE THIS: Build the erp.shipments definition one column and constraint at a time from the reference block below.

5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/sqlserver/source/02_create_erp_tables.sql in VS Code beside the database editor.
4. TYPE THIS: Build the erp.shipments definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.shipments
(
    shipment_id      BIGINT NOT NULL CONSTRAINT PK_shipments PRIMARY KEY,
    order_id         BIGINT NOT NULL,
    carrier          NVARCHAR(100) NOT NULL,
    tracking_number   VARCHAR(100) NOT NULL,
    ship_date        DATE NOT NULL,
    promised_delivery_date DATE NOT NULL,
    actual_delivery_date DATE NULL,
    shipment_status  VARCHAR(30) NOT NULL,
    shipping_cost     DECIMAL(12,2) NOT NULL,
    created_at       DATETIME2(3) NOT NULL,
    updated_at       DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_shipments_tracking UNIQUE (tracking_number),
    CONSTRAINT FK_shipments_order FOREIGN KEY (order_id) REFERENCES erp.orders(order_id)
);
```

Line-by-line DDL explanation

- **Line 1:** `CREATE TABLE erp.shipments` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `erp.shipments` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `shipment_id BIGINT NOT NULL CONSTRAINT PK_shipments PRIMARY KEY,` — `shipment_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BIGINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PK_shipments` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

tion; FK_shipments_order is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; FOREIGN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; order_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; REFERENCES is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; erp.orders is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; order_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 16:**) ; —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S11.V — Verify metadata and row count for erp.shipments

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.shipments;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.shipments;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.shipments` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.

- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.shipments`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_shipments_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.shipments` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 12 — `erp.inventory_transactions`

Real-world object: `inventory_transactions` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per inventory movement identifier. Verify that every column and example row describes that same unit.

Primary key: `inventory_transaction_id`

Foreign keys: `store_id` → `stores.store_id`; `product_id` → `products.product_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
<code>inventory_transaction_id</code>	BIGINT	No	Yes	—	Inventory movement identifier	9400001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
<code>store_id</code>	INT	No	No	<code>stores.store_id</code>	Inventory location	201	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
<code>product_id</code>	INT	No	No	<code>products.product_id</code>	Inventory product	10001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
transaction_timestamp	DATETIME2	No	No	—	Movement timestamp	2026-01-04T14:22:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
transaction_type	VARCHAR(30)	No	No	—	RECEIPT, SALE, RETURN, ADJUSTMENT, or TRANSFER	SALE	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
quantity_change	INT	No	No	—	Signed quantity change	-2	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
reference_type	VARCHAR(30)	Yes	No	—	Related object type	ORDER	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
reference_id	VARCHAR(60)	Yes	No	—	Related identifier	9000001	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
unit_cost	DECIMAL(12,2)	Yes	No	—	Cost for valuation	18.50	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Nullable because the source can legitimately omit it
created_at	DATETIME2	No	No	—	Source creation timestamp	2026-01-04T14:22:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- inventory_transaction_id = 40000001
- store_id = 201

- `product_id = 10005`
- `transaction_timestamp = 2026-07-01T00:00:00`
- `transaction_type = OPENING`
- `quantity_change = 75`
- `reference_type = SYNTHETIC`
- `reference_id = ```
- `created_at = 2026-08-15T12:00:00`

Action 4.4.S12 — Create and inspect `erp.inventory_transactions`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.inventory_transactions`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to `master`, `postgres`, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.inventory_transactions` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/`F5` only after the database selector shows `NorthstarRetail_ERP`.
8. LOOK FOR: No error in the Messages pane and the table under `NorthstarRetail_ERP > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to `master`, `postgres`, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.inventory_transactions` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.

6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.inventory_transactions
(
    inventory_transaction_id BIGINT NOT NULL CONSTRAINT PK_inventory_transactions PRIMARY KEY,
    store_id INT NOT NULL,
    product_id INT NOT NULL,
    transaction_timestamp DATETIME2(3) NOT NULL,
    transaction_type VARCHAR(30) NOT NULL,
    quantity_change INT NOT NULL,
    reference_type VARCHAR(30) NULL,
    reference_id BIGINT NULL,
    created_at DATETIME2(3) NOT NULL,
    CONSTRAINT FK_inventory_transactions_store FOREIGN KEY (store_id) REFERENCES erp.stores(store_id),
    CONSTRAINT FK_inventory_transactions_product FOREIGN KEY (product_id) REFERENCES erp.products(product_id)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE erp.inventory_transactions — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.inventory_transactions is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- [illegible]

- **Line 11:** `created_at DATETIME2(3) NOT NULL`, — `created_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DATETIME2` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `3` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 12:** `CONSTRAINT FK_inventory_transactions_store FOREIGN KEY (store_id) REFERENCES erp.stores(store_id)`, — `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FK_inventory_transactions_store` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FOREIGN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `store_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `REFERENCES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `erp.stores` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `store_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 13:** `CONSTRAINT FK_inventory_transactions_product FOREIGN KEY (product_id) REFERENCES erp.products(product_id)` — `CONSTRAINT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FK_inventory_transactions_product` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FOREIGN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `product_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `REFERENCES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `erp.products` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `product_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 14:** `);` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S12.V — Verify metadata and row count for `erp.inventory_transactions`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.inventory_transactions;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to NorthstarRetail_ERP. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.inventory_transactions;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.inventory_transactions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.inventory_transactions`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_inventory_transactions_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.inventory_transactions` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 13 — `erp.inventory_snapshots`

Real-world object: `inventory_snapshots` in the SQL Server ERP domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to SQL Server ERP; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per snapshot row identifier. Verify that every column and example row describes that same unit.

Primary key: `inventory_snapshot_id`

Foreign keys: `store_id` → `stores.store_id`; `product_id` → `products.product_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
inventory_snapshot_id	BIGINT	No	Yes	—	Snapshot row identifier	9500001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
snapshot_date	DATE	No	No	—	Snapshot date	2026-01-31	a calendar date with no time-of-day component. Required because the business record is incomplete without it
store_id	INT	No	No	stores.store_id	Inventory location	201	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
product_id	INT	No	No	products.product_id	Inventory product	10001	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
on_hand_quantity	INT	No	No	—	Units physically on hand	42	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
reserved_quantity	INT	No	No	—	Units reserved for open orders	3	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it
reorder_point	INT	No	No	—	Threshold for replenishment	10	a whole-number type for identifiers, counts, flags represented as numbers, or day values. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
source_updated_at	DATETIME2	No	No	—	Source calculation time	2026-01-31T23:59:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
created_at	DATETIME2	No	No	—	Source creation timestamp	2026-02-01T00:05:00	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- inventory_snapshot_id = 50000001
- snapshot_date = 2026-07-31
- store_id = 201
- product_id = 10005
- quantity_on_hand = 88
- quantity_reserved = 8
- reorder_point = 13
- created_at = 2026-08-15T12:00:00

Action 4.4.S13 — Create and inspect `erp.inventory_snapshots`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Create and inspect `erp.inventory_snapshots`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is `NorthstarRetail_ERP` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.inventory_snapshots` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with `Ctrl+S` before execution.

6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **SQL Server Management Studio (SSMS)**.
2. LOOK FOR: Confirm the active connection is NorthstarRetail_ERP and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/sqlserver/source/02_create_erp_tables.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `erp.inventory_snapshots` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows NorthstarRetail_ERP.
8. LOOK FOR: No error in the Messages pane and the table under NorthstarRetail_ERP > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: T-SQL

Exact file: sql/sqlserver/source/02_create_erp_tables.sql

Execution location: SQL Server Management Studio (SSMS), database NorthstarRetail_ERP.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE erp.inventory_snapshots
(
    inventory_snapshot_id BIGINT NOT NULL CONSTRAINT PK_inventory_snapshots PRIMARY KEY,
    snapshot_date         DATE NOT NULL,
    store_id              INT NOT NULL,
    product_id            INT NOT NULL,
    quantity_on_hand      INT NOT NULL,
    quantity_reserved     INT NOT NULL,
    reorder_point         INT NOT NULL,
    created_at            DATETIME2(3) NOT NULL,
    CONSTRAINT UQ_inventory_snapshot_grain UNIQUE (snapshot_date, store_id, product_id),
    CONSTRAINT FK_inventory_snapshots_store FOREIGN KEY (store_id) REFERENCES erp.stores(store_id),
    CONSTRAINT FK_inventory_snapshots_product FOREIGN KEY (product_id) REFERENCES erp.products(product_id)
);
```

Line-by-line DDL explanation

- Line 1:** CREATE TABLE erp.inventory_snapshots — CREATE defines a new database object; TABLE the database object that stores rows and columns; erp.inventory_snapshots is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S13.V — Verify metadata and row count for `erp.inventory_snapshots`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM erp.inventory_snapshots;
```

Where to enter it:

SQL Server Management Studio (SSMS) query window connected to `NorthstarRetail_ERP`. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM erp.inventory_snapshots;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `erp.inventory_snapshots` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `erp.inventory_snapshots`

Show SQL Server Management Studio (SSMS) with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_erp_inventory_snapshots_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `erp.inventory_snapshots` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 14 — digital.web_users

Real-world object: web_users in the PostgreSQL Digital domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to PostgreSQL Digital; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per digital user identifier. Verify that every column and example row describes that same unit.

Primary key: web_user_id

Foreign keys: No foreign key; this object is a parent/reference table or independent event table.

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
web_user_id	BIGINT	No	Yes	—	Digital user identifier	700001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
web_user_key	VARCHAR(40)	No	No	—	Digital business key	WU-700001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
customer_id	INTEGER	Yes	No	—	Loose ERP customer reference	100001	the storage type selected for the business meaning and source-system behavior of this column. Nullable because the source can legitimately omit it
email	VARCHAR(255)	Yes	No	—	Synthetic login email	visitor@example.test	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
registration_timestamp	TIMESTAMPTZ	No	No	—	Registration time	2026-01-01T12:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
country_code	VARCHAR(10)	No	No	—	Country code	US	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
marketing_consent	BOOLEAN	No	No	—	Marketing consent	true	a true/false flag. Required because the business record is incomplete without it
created_at	TIMESTAMPZ	No	No	—	Source creation time	2026-01-01T12:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	TIMESTAMPZ	No	No	—	Source update time	2026-01-01T12:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- web_user_id = 700001
- customer_id = 100051.0
- anonymous_cookie_id = f5d63f1e27baff0434521fc83e64e93b
- email_hash = 3120ff119c3b5dfdf8a1a71723efccd7f3ae150e90c6dd78d0dfba39c6848457
- created_at = 2023-08-16T00:00:00
- updated_at = 2026-08-15T12:00:00

Action 4.4.S14 — Create and inspect digital.web_users

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect digital.web_users. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.web_users definition one column and constraint at a time from the reference block below.

5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.web_users definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DDL section — build and explain it before execution

Language: PostgreSQL SQL

Exact file: sql/postgres/source/01_create_digital_schema.sql

Execution location: pgAdmin 4 Query Tool, database northstar_digital.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE IF NOT EXISTS digital.web_users
(
    web_user_id          bigint PRIMARY KEY,
    customer_id          integer NULL,
    anonymous_cookie_id  varchar(64) NOT NULL,
    email_hash           char(64) NULL,
    created_at           timestamptz NOT NULL,
    updated_at           timestamptz NOT NULL,
    CONSTRAINT uq_web_users_cookie UNIQUE (anonymous_cookie_id)
);
```

Line-by-line DDL explanation

- **Line 1:** `CREATE TABLE IF NOT EXISTS digital.web_users` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `IF` begins a conditional decision; `NOT` reverses a Boolean condition; `EXISTS` tests whether a matching object or row is present; `digital.web_users` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `web_user_id bigint PRIMARY KEY,` — `web_user_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `bigint` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `customer_id integer NULL,` — `customer_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `integer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `anonymous_cookie_id varchar(64) NOT NULL,` — `anonymous_cookie_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `varchar` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `64` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `email_hash char(64) NULL,` — `email_hash` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `char` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `64` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `created_at timestamptz NOT NULL,` — `created_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `timestamptz` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `updated_at timestamptz NOT NULL,` — `updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `timestamptz` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition;

NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 9:** CONSTRAINT uq_web_users_cookie UNIQUE (anonymous_cookie_id) — CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; uq_web_users_cookie is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; UNIQUE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; anonymous_cookie_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 10:**) ; —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S14.V — Verify metadata and row count for digital.web_users

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

pgAdmin 4 Query Tool query window connected to northstar_digital

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM digital.web_users;
```

Where to enter it:

pgAdmin 4 Query Tool query window connected to northstar_digital. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM digital.web_users;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `digital.web_users` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Recommended filename: docs/images/phase04_digital_web_users_schema_verified.png. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled digital.web_users at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 15 — digital.campaigns

Real-world object: campaigns in the PostgreSQL Digital domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to PostgreSQL Digital; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per campaign identifier. Verify that every column and example row describes that same unit.

Primary key: campaign_id

Foreign keys: No foreign key; this object is a parent/reference table or independent event table.

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
campaign_id	INTEGER	No	Yes	—	Campaign identifier	801	the storage type selected for the business meaning and source-system behavior of this column. Required because the business record is incomplete without it
campaign_code	VARCHAR(40)	No	No	—	Campaign business key	CMP-0801	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
campaign_name	VARCHAR(150)	No	No	—	Campaign name	Winter Essentials	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
channel	VARCHAR(30)	No	No	—	Marketing channel	PAID_SEARCH	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
start_date	DATE	No	No	—	Campaign start	2026-01-01	a calendar date with no time-of-day component. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
end_date	DATE	No	No	—	Campaign end	2026-01-31	a calendar date with no time-of-day component. Required because the business record is incomplete without it
budget_amount	NUMERIC(14,2)	No	No	—	Planned spend	2500.00	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
currency_code	CHAR(3)	No	No	—	Budget currency	USD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
objective	VARCHAR(60)	No	No	—	Campaign objective	CONVERSION	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
created_at	TIMESTAMPZ	No	No	—	Source creation time	2025-12-15T12:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
updated_at	TIMESTAMPZ	No	No	—	Source update time	2025-12-15T12:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- campaign_id = 8001
- campaign_code = CMP-08001
- campaign_name = Seasonal Campaign 1
- channel = Email
- start_date = 2025-10-02
- end_date = 2025-11-16
- budget_amount = 18670.77
- currency_code = USD
- created_at = 2025-10-02T00:00:00

Action 4.4.S15 — Create and inspect digital.campaigns

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect digital.campaigns. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.campaigns definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.campaigns definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: PostgreSQL SQL

Exact file: sql/postgres/source/01_create_digital_schema.sql

Execution location: pgAdmin 4 Query Tool, database northstar_digital.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE IF NOT EXISTS digital.campaigns
(
    campaign_id      integer PRIMARY KEY,
    campaign_code    varchar(30) NOT NULL UNIQUE,
    campaign_name     varchar(200) NOT NULL,
    channel          varchar(40) NOT NULL,
    start_date       date NOT NULL,
    end_date         date NOT NULL,
    budget_amount    numeric(14,2) NOT NULL,
    currency_code     varchar(3) NOT NULL,
    created_at       timestampz NOT NULL,
    updated_at       timestampz NOT NULL,
    CONSTRAINT ck_campaign_dates CHECK (end_date >= start_date)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE IF NOT EXISTS digital.campaigns — CREATE defines a new database object; TABLE the database object that stores rows and columns; IF begins a conditional decision; NOT reverses a Boolean condition; EXISTS tests whether a matching object or row is present; digital.campaigns is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** campaign_id integer PRIMARY KEY, — campaign_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; integer is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PRIMARY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, ar-

gument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

er, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 12:** updated_at timestamptz NOT NULL, — updated_at is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; timestamptz is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 13:** CONSTRAINT ck_campaign_dates CHECK (end_date >= start_date) — CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; ck_campaign_dates is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CHECK is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; end_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; >= is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; start_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 14:**); —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S15.V — Verify metadata and row count for digital.campaigns

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

pgAdmin 4 Query Tool query window connected to northstar_digital

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM digital.campaigns;
```

Where to enter it:

pgAdmin 4 Query Tool query window connected to northstar_digital. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM digital.campaigns;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `digital.campaigns` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record VERIFIED BY USER and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for digital.campaigns

Show pgAdmin 4 Query Tool with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: docs/images/phase04_digital_campaigns_schema_verified.png. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled digital.campaigns at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 16 — digital.web_sessions

Real-world object: web_sessions in the PostgreSQL Digital domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to PostgreSQL Digital; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per session identifier. Verify that every column and example row describes that same unit.

Primary key: session_id

Foreign keys: web_user_id → web_users.web_user_id; campaign_id → campaigns.campaign_id

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
session_id	BIGINT	No	Yes	—	Session identifier	7100001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
session_key	VARCHAR(50)	No	No	—	Session business key; controlled duplicates included	SES-07100001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
web_user_id	BIGINT	Yes	No	web_users.web_user_id	Known digital user	700001	a whole-number type used where identifiers or counts may exceed the normal integer range. Nullable because the source can legitimately omit it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
session_start	TIMESTAMPZ	No	No	—	Session start time	2026-01-04T14:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
session_end	TIMESTAMPZ	Yes	No	—	Session end time	2026-01-04T14:17:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Nullable because the source can legitimately omit it
device_type	VARCHAR(30)	No	No	—	Desktop, mobile, or tablet	MOBILE	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
traffic_source	VARCHAR(50)	No	No	—	Acquisition source	google	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
campaign_id	INTEGER	Yes	No	campaigns.campaign_id	Attributed campaign	801	the storage type selected for the business meaning and source-system behavior of this column. Nullable because the source can legitimately omit it
landing_page	VARCHAR(300)	No	No	—	First page	/category/electronics	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
converted_order_id	BIGINT	Yes	No	—	Loose ERP order reference	9000001	a whole-number type used where identifiers or counts may exceed the normal integer range. Nullable because the source can legitimately omit it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
created_at	TIMESTAMPZ	No	No	—	Source creation time	2026-01-04T14:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- session_id = 1000001
- web_user_id = 700047
- session_start_utc = 2025-08-23T04:30:18-04:00
- session_end_utc = 2025-08-23T08:30:48+00:00
- source_channel = Direct
- campaign_id = ``
- device_type = mobile
- country_code = US
- converted_order_id = ``
- created_at = 2026-08-15T12:00:00+00:00

Action 4.4.S16 — Create and inspect digital.web_sessions

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect digital.web_sessions. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.web_sessions definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL `psql`, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is `northstar_digital` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/postgres/source/01_create_digital_schema.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `digital.web_sessions` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `northstar_digital`.
8. LOOK FOR: No error in the Messages pane and the table under `northstar_digital > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: PostgreSQL SQL

Exact file: `sql/postgres/source/01_create_digital_schema.sql`

Execution location: pgAdmin 4 Query Tool, database `northstar_digital`.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE IF NOT EXISTS digital.web_sessions
(
  session_id          bigint PRIMARY KEY,
  web_user_id         bigint NULL REFERENCES digital.web_users(web_user_id),
  session_start_utc   timestampz NOT NULL,
  session_end_utc     timestampz NULL,
  source_channel       varchar(40) NOT NULL,
  campaign_id         integer NULL REFERENCES digital.campaigns(campaign_id),
  device_type         varchar(30) NOT NULL,
  country_code        varchar(10) NOT NULL,
  converted_order_id  bigint NULL,
  created_at          timestampz NOT NULL,
  CONSTRAINT ck_session_end CHECK (session_end_utc IS NULL OR session_end_utc >= session_start_utc)
);
```

Line-by-line DDL explanation

- **Line 1:** `CREATE TABLE IF NOT EXISTS digital.web_sessions` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `IF` begins a conditional decision; `NOT` reverses a Boolean condition; `EXISTS` tests whether a matching object or row is present; `digital.web_sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `session_id bigint PRIMARY KEY,` — `session_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `bigint` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `web_user_id bigint NULL REFERENCES digital.web_users(web_user_id),` — `web_user_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `bigint` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `REFERENCES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `digital.web_users` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `web_user_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)`, is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `session_start_utc timestampz NOT NULL,` — `session_start_utc` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `timestampz` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `session_end_utc timestampz NULL,` — `session_end_utc` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `timestampz` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `source_channel varchar(40) NOT NULL,` — `source_channel` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `varchar` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `40` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `campaign_id integer NULL REFERENCES digital.campaigns(campaign_id),` — `campaign_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `integer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `REFERENCES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `digital.campaigns` is a name, keyword, argument, identifier, or literal

whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; campaign_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;), is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S16.V — Verify metadata and row count for digital.web_sessions

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

pgAdmin 4 Query Tool query window connected to northstar_digital

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM digital.web_sessions;
```

Where to enter it:

pgAdmin 4 Query Tool query window connected to northstar_digital. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM digital.web_sessions;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `digital.web_sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `digital.web_sessions`

Show pgAdmin 4 Query Tool with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_digital_web_sessions_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `digital.web_sessions` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 17 — `digital.web_events`

Real-world object: `web_events` in the PostgreSQL Digital domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to PostgreSQL Digital; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per event row identifier. Verify that every column and example row describes that same unit.

Primary key: `event_id`

Foreign keys: `session_id` → `web_sessions.session_id`

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
event_id	BIGINT	No	Yes	—	Event row identifier	7200001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
event_key	VARCHAR(50)	No	No	—	Event business key; controlled duplicates included	EVT-07200001	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
session_id	BIGINT	No	No	web_sessions.session_id	Parent session	7100001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
event_timestamp	TIMESTAMPZ	No	No	—	Event time	2026-01-04T14:02:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
event_type	VARCHAR(40)	No	No	—	PAGE_VIEW, PRODUCT_VIEW, ADD_TO_CART, CHECKOUT, PURCHASE	PRODUCT_VIEW	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
page_url	VARCHAR(500)	Yes	No	—	Page URL	/product/NRT-ELE-10001	text with either a stated maximum length or engine-managed variable length. Nullable because the source can legitimately omit it
product_id	INTEGER	Yes	No	—	Loose ERP product reference	10001	the storage type selected for the business meaning and source-system behavior of this column. Nullable because the source can legitimately omit it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
order_id	BIGINT	Yes	No	—	Loose ERP order reference	9000001	a whole-number type used where identifiers or counts may exceed the normal integer range. Nullable because the source can legitimately omit it
event_properties	JSONB	No	No	—	Flexible event payload	{"position":1}	structured JSON content that can preserve nested attributes. Required because the business record is incomplete without it
created_at	TIMESTAMPTZ	No	No	—	Source creation time	2026-01-04T14:02:01Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- event_id = 2000001
- session_id = 1000001
- event_timestamp = 2020-01-01T00:00:00+00:00
- event_type = page_view
- page_url = https://northstar.example/page-view
- product_id = ``
- order_id = ``
- event_properties = {"synthetic": true, "sequence": 0}
- created_at = 2026-08-15T12:00:00+00:00

Action 4.4.S17 — Create and inspect digital.web_events

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect digital.web_events. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **pgAdmin 4 Query Tool**.

2. LOOK FOR: Confirm the active connection is `northstar_digital` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/postgres/source/01_create_digital_schema.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `digital.web_events` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `northstar_digital`.
8. LOOK FOR: No error in the Messages pane and the table under `northstar_digital > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is `northstar_digital` and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open `sql/postgres/source/01_create_digital_schema.sql` in VS Code beside the database editor.
4. TYPE THIS: Build the `digital.web_events` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `northstar_digital`.
8. LOOK FOR: No error in the Messages pane and the table under `northstar_digital > Tables` after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: PostgreSQL SQL

Exact file: sql/postgres/source/01_create_digital_schema.sql

Execution location: pgAdmin 4 Query Tool, database northstar_digital.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE IF NOT EXISTS digital.web_events
(
    event_id          bigint PRIMARY KEY,
    session_id        bigint NOT NULL REFERENCES digital.web_sessions(session_id),
    event_timestamp    timestampz NOT NULL,
    event_type         varchar(50) NOT NULL,
    page_url           text NULL,
    product_id         integer NULL,
    order_id           bigint NULL,
    event_properties    jsonb NULL,
    created_at         timestampz NOT NULL
);
```

Line-by-line DDL explanation

- Line 1:** `CREATE TABLE IF NOT EXISTS digital.web_events` — `CREATE` defines a new database object; `TABLE` the database object that stores rows and columns; `IF` begins a conditional decision; `NOT` reverses a Boolean condition; `EXISTS` tests whether a matching object or row is present; `digital.web_events` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 2:** `(` — `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 3:** `event_id bigint PRIMARY KEY,` — `event_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `bigint` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `PRIMARY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `KEY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 4:** `session_id bigint NOT NULL REFERENCES digital.web_sessions(session_id),` — `session_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `bigint` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `REFERENCES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `digital.web_sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `session_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `),` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 5:** `event_timestamp timestampz NOT NULL,` — `event_timestamp` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `timestampz` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- Line 6:** `event_type varchar(50) NOT NULL,` — `event_type` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `varchar` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `50` is a numeric literal used by the command or expression; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

tifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** `page_url text NULL`, — `page_url` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `text` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `product_id integer NULL`, — `product_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `integer` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** `order_id bigint NULL`, — `order_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `bigint` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 10:** `event_properties jsonb NULL`, — `event_properties` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `jsonb` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 11:** `created_at timestamptz NOT NULL` — `created_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `timestamptz` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOT` reverses a Boolean condition; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 12:** `);` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S17.V — Verify metadata and row count for `digital.web_events`

Application:

pgAdmin 4 or PostgreSQL `psql`, as named in the action

Window or panel:

pgAdmin 4 Query Tool query window connected to `northstar_digital`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM digital.web_events;
```

Where to enter it:

pgAdmin 4 Query Tool query window connected to northstar_digital. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM digital.web_events;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `digital.web_events` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record VERIFIED BY USER and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for digital.web_events

Show pgAdmin 4 Query Tool with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: docs/images/phase04_digital_web_events_schema_verified.png. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled digital.web_events at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 18 — digital.campaign_touchpoints

Real-world object: campaign touchpoints in the PostgreSQL Digital domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to PostgreSQL Digital; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per marketing touchpoint identifier. Verify that every column and example row describes that same unit.

Primary key: touchpoint_id

Foreign keys: campaign_id → campaigns.campaign_id; web_user_id → web_users.web_user_id; session_id → web_sessions.session_id

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
touchpoint_id	BIGINT	No	Yes	—	Marketing touchpoint identifier	7300001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
campaign_id	INTEGER	No	No	campaigns.campaign_id	Campaign	801	the storage type selected for the business meaning and source-system behavior of this column. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
web_user_id	BIGINT	Yes	No	web_users.web_user_id	Known user	700001	a whole-number type used where identifiers or counts may exceed the normal integer range. Nullable because the source can legitimately omit it
session_id	BIGINT	Yes	No	web_sessions.session_id	Related session	7100001	a whole-number type used where identifiers or counts may exceed the normal integer range. Nullable because the source can legitimately omit it
touchpoint_timestamp	TIMESTAMPZ	No	No	—	Touchpoint time	2026-01-04T13:58:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it
touchpoint_type	VARCHAR(30)	No	No	—	IMPRESSION, CLICK, EMAIL_OPEN, or EMAIL_CLICK	CLICK	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
cost_amount	NUMERIC(12,4)	No	No	—	Allocated cost	0.8500	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
currency_code	CHAR(3)	No	No	—	Cost currency	USD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
created_at	TIMESTAMPZ	No	No	—	Source creation time	2026-01-04T13:58:01Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- touchpoint_id = 3000001

- web_user_id = 700079
- session_id = 1000002
- campaign_id = 8008
- touchpoint_timestamp = 2025-07-20T11:58:52+00:00
- touchpoint_type = click
- attribution_weight = 1.0
- created_at = 2026-08-15T12:00:00+00:00

Action 4.4.S18 — Create and inspect digital.campaign_touchpoints

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect digital.campaign_touchpoints. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.campaign_touchpoints definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.campaign_touchpoints definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.

6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: PostgreSQL SQL

Exact file: sql/postgres/source/01_create_digital_schema.sql

Execution location: pgAdmin 4 Query Tool, database northstar_digital.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE IF NOT EXISTS digital.campaign_touchpoints
(
    touchpoint_id      bigint PRIMARY KEY,
    web_user_id        bigint NULL REFERENCES digital.web_users(web_user_id),
    session_id         bigint NULL REFERENCES digital.web_sessions(session_id),
    campaign_id        integer NOT NULL REFERENCES digital.campaigns(campaign_id),
    touchpoint_timestamp timestampz NOT NULL,
    touchpoint_type     varchar(40) NOT NULL,
    attribution_weight  numeric(8,6) NOT NULL,
    created_at         timestampz NOT NULL,
    CONSTRAINT ck_touchpoint_weight CHECK (attribution_weight >= 0 AND attribution_weight <= 1)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE IF NOT EXISTS digital.campaign_touchpoints — CREATE defines a new database object; TABLE the database object that stores rows and columns; IF begins a conditional decision; NOT reverses a Boolean condition; EXISTS tests whether a matching object or row is present; digital.campaign_touchpoints is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 10:** created_at timestampz NOT NULL, — created_at is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; timestampz is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 11:** CONSTRAINT ck_touchpoint_weight CHECK (attribution_weight >= 0 AND attribution_weight <= 1) — CONSTRAINT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; ck_touchpoint_weight is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; CHECK is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; attribution_weight is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; >= is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression; AND is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; attribution_weight is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; <= is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 1 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 12:**); —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S18.V — Verify metadata and row count for digital.campaign_touchpoints

Application:

pgAdmin 4 or PostgreSQL psqL, as named in the action

Window or panel:

pgAdmin 4 Query Tool query window connected to northstar_digital

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psqL, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.

6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM digital.campaign_touchpoints;
```

Where to enter it:

pgAdmin 4 Query Tool query window connected to northstar_digital. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM digital.campaign_touchpoints;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `digital.campaign_touchpoints` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record VERIFIED BY USER and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for digital.campaign_touchpoints

Show pgAdmin 4 Query Tool with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: docs/images/phase04_digital_campaign_touchpoints_schema_verified.png. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled digital.campaign_touchpoints at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

Source object 19 — digital.marketing_spend

Real-world object: marketing_spend in the PostgreSQL Digital domain.

Why it belongs in this source: The object is generated and operated with the transaction or digital behavior assigned to PostgreSQL Digital; the placement creates a realistic heterogeneous integration boundary.

Declared grain: one row per spend row identifier. Verify that every column and example row describes that same unit.

Primary key: marketing_spend_id

Foreign keys: campaign_id → campaigns.campaign_id

Index purpose: Primary, unique, foreign-key, timestamp, and business-key indexes support integrity or extraction access patterns; do not add indexes without a query reason.

Column-by-column design

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
marketing_spend_id	BIGINT	No	Yes	—	Spend row identifier	7400001	a whole-number type used where identifiers or counts may exceed the normal integer range. Required because the business record is incomplete without it
spend_date	DATE	No	No	—	Spend date	2026-01-04	a calendar date with no time-of-day component. Required because the business record is incomplete without it

Column	Data type	Null?	PK	FK	Business definition	Example	Why the type/constraint fits
campaign_id	INTEGER	No	No	campaigns.campaign_id	Campaign	801	the storage type selected for the business meaning and source-system behavior of this column. Required because the business record is incomplete without it
channel	VARCHAR(30)	No	No	—	Marketing channel	PAID_SEARCH	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
spend_amount	NUMERIC(14,2)	No	No	—	Actual spend	125.40	an exact fixed-precision number suitable for currency or ratios where binary floating-point rounding is undesirable. Required because the business record is incomplete without it
currency_code	CHAR(3)	No	No	—	Spend currency	USD	text with either a stated maximum length or engine-managed variable length. Required because the business record is incomplete without it
impressions	INTEGER	No	No	—	Delivered impressions	25000	the storage type selected for the business meaning and source-system behavior of this column. Required because the business record is incomplete without it
clicks	INTEGER	No	No	—	Clicks	680	the storage type selected for the business meaning and source-system behavior of this column. Required because the business record is incomplete without it
created_at	TIMESTAMPZ	No	No	—	Source creation time	2026-01-05T02:00:00Z	a date-and-time value used for event time, creation time, update time, or incremental watermarks. Required because the business record is incomplete without it

Realistic example record

- spend_id = 4000001
- spend_date = 2025-10-02
- campaign_id = 8001
- channel = Email
- spend_amount = 678.34
- impressions = 25257
- clicks = 1259
- currency_code = USD
- created_at = 2026-08-15T12:00:00+00:00

Action 4.4.S19 — Create and inspect digital.marketing_spend

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create and inspect digital.marketing_spend. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.
4. TYPE THIS: Build the digital.marketing_spend definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows northstar_digital.
8. LOOK FOR: No error in the Messages pane and the table under northstar_digital > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL psql, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open **pgAdmin 4 Query Tool**.
2. LOOK FOR: Confirm the active connection is northstar_digital and the query editor is not connected to master, postgres, or another database.
3. CLICK: Open sql/postgres/source/01_create_digital_schema.sql in VS Code beside the database editor.

4. TYPE THIS: Build the `digital.marketing_spend` definition one column and constraint at a time from the reference block below.
5. PRESS: Save the source file with Ctrl+S before execution.
6. CLICK: Copy only this table's current verified DDL into a new query window or use the phase's full ordered script after every table section is understood.
7. PRESS: Execute/F5 only after the database selector shows `northstar_digital`.
8. LOOK FOR: No error in the Messages pane and the table under `northstar_digital` > Tables after Refresh.
9. CLICK: Expand Columns, Keys, Constraints, and Indexes to compare them with the design table.
10. DO NOT CONTINUE UNTIL: A metadata query confirms the column names and types.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

DDL section — build and explain it before execution

Language: PostgreSQL SQL

Exact file: `sql/postgres/source/01_create_digital_schema.sql`

Execution location: pgAdmin 4 Query Tool, database `northstar_digital`.

Input: The requirements and column design above.

Output: One table plus its constraints and indexes when the statement is run in the correct database.

```
CREATE TABLE IF NOT EXISTS digital.marketing_spend
(
    spend_id          bigint PRIMARY KEY,
    spend_date        date NOT NULL,
    campaign_id       integer NOT NULL REFERENCES digital.campaigns(campaign_id),
    channel           varchar(40) NOT NULL,
    spend_amount      numeric(14,2) NOT NULL,
    impressions       bigint NOT NULL,
    clicks            bigint NOT NULL,
    currency_code     varchar(3) NOT NULL,
    created_at        timestamptz NOT NULL,
    CONSTRAINT uq_marketing_spend_grain UNIQUE (spend_date, campaign_id, channel),
    CONSTRAINT ck_spend_nonnegative CHECK (spend_amount >= 0 AND impressions >= 0 AND clicks >= 0)
);
```

Line-by-line DDL explanation

- **Line 1:** CREATE TABLE IF NOT EXISTS digital.marketing_spend — CREATE defines a new database object; TABLE the database object that stores rows and columns; IF begins a conditional decision; NOT reverses a Boolean condition; EXISTS tests whether a matching object or row is present; digital.marketing_spend is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** spend_id bigint PRIMARY KEY, — spend_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; bigint is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; PRIMARY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; KEY is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 14:** `);` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Verification query

Action 4.4.S19.V — Verify metadata and row count for `digital.marketing_spend`

Application:

pgAdmin 4 or PostgreSQL `psql`, as named in the action

Window or panel:

pgAdmin 4 Query Tool query window connected to `northstar_digital`

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained SQL instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4** or **PostgreSQL psql**, as named in the action to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (SQL):

```
SELECT COUNT(*) AS row_count FROM digital.marketing_spend;
```

Where to enter it:

pgAdmin 4 Query Tool query window connected to northstar_digital. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT(*) AS row_count FROM digital.marketing_spend;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `row_count` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `FROM` identifies the source table or query; `digital.marketing_spend` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Object-already-exists branch

- **If the script reports that the object already exists:** Do not drop it automatically. Inspect its columns, keys, constraints, and origin. Compare with Git history and your journal.
- **If the object matches exactly and was created by your verified earlier run:** Record `VERIFIED BY USER` and proceed without recreating it.
- **If it differs:** Script or document the existing definition, preserve evidence, and decide whether to migrate it or use the documented development reset only after confirming that no needed data will be lost.
- **If the table is empty:** That is expected before Phase 6. Do not treat zero rows as a schema failure.
- **If rows already exist:** Record the count and source before any load; never silently append to an unknown baseline.

Screenshot checkpoint for `digital.marketing_spend`

Show pgAdmin 4 Query Tool with Object Explorer/server tree, the expanded table columns, and the successful metadata query. Hide login names, server addresses beyond localhost, and credentials. Recommended filename: `docs/images/phase04_digital_marketing_spend_schema_verified.png`. This screenshot proves the definition you inspected, not that later data loads succeeded.

Interview-ready explanation

"I modeled `digital.marketing_spend` at the declared grain, selected types and nullability from business meaning, enforced stable identifiers and relationships, and verified the physical schema independently rather than assuming the DDL ran correctly."

[Back to the Phase 4 lesson index](#)

File-feed object 1 — `returns.csv`

Purpose: one row per returned product line, including quantity, reason, status, and dates.

Physical format: `csv`. CSV is flat and inspectable; JSON Lines keeps one independently parseable event per line and supports nested content.

Expected generated location: `datasets/raw/files/returns.csv` inside a batch-controlled extract/output structure.

Grain: one row per returned product line, including quantity, reason, status, and dates.

Dependencies: Generated parent/business keys must correspond to valid source data except for explicitly injected quality-test cases.

Downstream targets: `bronze.file_returns`, an entity-specific Silver table or quarantine, and the mapped Gold dimension/fact when applicable.

Action 4.4.FD1 — Inspect and reconcile `returns.csv`

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Inspect and reconcile `returns.csv`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: In VS Code Explorer, expand `datasets`, then `raw`, then `files` only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `returns.csv` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: In VS Code Explorer, expand `datasets`, then `raw`, then `files` only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `returns.csv` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

Expected example — do not type this as output

```
return_id,order_id,order_item_id,product_id,customer_id,return_date,return_quantity,return_reason,refund_amount,currency_code,source_file_date
RET-00000001,9000071,10000142,99999999,100013,04/22/2025,1,Late delivery,140.14,USD,2025-01-01
RET-00000002,9000175,10000353,100000000,100034,20-Mar-2026,1,Wrong size,29.73,USD,2025-01-01
RET-00000003,9000123,10000237,10026,100009,2024/06/29,1,Changed mind,15.04,USD,2026-08-15
```

What to validate

1. The file exists only after the generator or extractor writes it.
2. The filename extension is not hidden or doubled, such as .csv.txt.
3. CSV headers are unique and match the data dictionary; JSON Lines has exactly one complete object per nonblank line.
4. The manifest count matches an independent count.
5. The SHA-256 checksum matches a fresh calculation.
6. Expected dirty rows remain observable for Silver tests; raw data is not “cleaned” manually.
7. No real customer or employee information is present; the data is fictional.

Git rule

Generated raw batches are normally ignored because they can be recreated and may be large. Small non-sensitive sample fixtures under datasets/sample/ can be tracked for tests. Confirm the rule with `git check-ignore -v` before staging.

Interview-ready explanation

“I treated returns.csv as a source contract with a declared grain, schema, manifest entry, checksum, and downstream mapping. I preserved raw evidence and corrected generation logic rather than editing an output file.”

File-feed object 2 — supplier_cost_updates.csv

Purpose: one row per supplier-product cost change effective on a business date.

Physical format: csv. CSV is flat and inspectable; JSON Lines keeps one independently parseable event per line and supports nested content.

Expected generated location: datasets/raw/files/supplier_cost_updates.csv inside a batch-controlled extract/output structure.

Grain: one row per supplier-product cost change effective on a business date.

Dependencies: Generated parent/business keys must correspond to valid source data except for explicitly injected quality-test cases.

Downstream targets: bronze.file_supplier_cost_updates, an entity-specific Silver table or quarantine, and the mapped Gold dimension/fact when applicable.

Action 4.4.FD2 — Inspect and reconcile supplier_cost_updates.csv**Application:**

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Inspect and reconcile `supplier_cost_updates.csv`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: In VS Code Explorer, expand datasets, then raw, then files only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `supplier_cost_updates.csv` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

SCU-00000003,SUP-05001,NRT-ELE-10002,2026-03-15,22.45,USD
```

What to validate

1. The file exists only after the generator or extractor writes it.
2. The filename extension is not hidden or doubled, such as .csv.txt.
3. CSV headers are unique and match the data dictionary; JSON Lines has exactly one complete object per nonblank line.
4. The manifest count matches an independent count.
5. The SHA-256 checksum matches a fresh calculation.
6. Expected dirty rows remain observable for Silver tests; raw data is not “cleaned” manually.
7. No real customer or employee information is present; the data is fictional.

Git rule

Generated raw batches are normally ignored because they can be recreated and may be large. Small non-sensitive sample fixtures under datasets/sample/ can be tracked for tests. Confirm the rule with `git check-ignore -v` before staging.

Interview-ready explanation

“I treated supplier_cost_updates.csv as a source contract with a declared grain, schema, manifest entry, checksum, and downstream mapping. I preserved raw evidence and corrected generation logic rather than editing an output file.”

File-feed object 3 — promotion_calendar.csv

Purpose: one row per promotion definition and active date range.

Physical format: csv. CSV is flat and inspectable; JSON Lines keeps one independently parseable event per line and supports nested content.

Expected generated location: datasets/raw/files/promotion_calendar.csv inside a batch-controlled extract/output structure.

Grain: one row per promotion definition and active date range.

Dependencies: Generated parent/business keys must correspond to valid source data except for explicitly injected quality-test cases.

Downstream targets: bronze.file_promotion_calendar, an entity-specific Silver table or quarantine, and the mapped Gold dimension/fact when applicable.

Action 4.4.FD3 — Inspect and reconcile promotion_calendar.csv**Application:**

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Inspect and reconcile `promotion_calendar.csv`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: In VS Code Explorer, expand datasets, then raw, then files only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `promotion_calendar.csv` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: In VS Code Explorer, expand datasets, then raw, then files only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `promotion_calendar.csv` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 4 lesson index](#)

Expected example — do not type this as output

```
promotion_code,promotion_name,start_date,end_date,discount_type,discount_value,channel_code
WELCOME10,New Customer Welcome,2025-01-01,2026-12-31,PERCENT,10,ONLINE
WEEKEND15,Weekend Event,2026-01-01,2026-12-31,PERCENT,15,ALL
FREESHIP,Free Shipping,2026-01-01,2026-12-31,SHIPPING,100,ONLINE
```

What to validate

1. The file exists only after the generator or extractor writes it.
2. The filename extension is not hidden or doubled, such as .csv.txt.
3. CSV headers are unique and match the data dictionary; JSON Lines has exactly one complete object per nonblank line.
4. The manifest count matches an independent count.
5. The SHA-256 checksum matches a fresh calculation.
6. Expected dirty rows remain observable for Silver tests; raw data is not “cleaned” manually.
7. No real customer or employee information is present; the data is fictional.

Git rule

Generated raw batches are normally ignored because they can be recreated and may be large. Small non-sensitive sample fixtures under datasets/sample/ can be tracked for tests. Confirm the rule with `git check-ignore -v` before staging.

Interview-ready explanation

“I treated promotion_calendar.csv as a source contract with a declared grain, schema, manifest entry, checksum, and downstream mapping. I preserved raw evidence and corrected generation logic rather than editing an output file.”

File-feed object 4 — shipment_tracking_events.jsonl

Purpose: one JSON object per carrier tracking event, with nested location/status details.

Physical format: jsonl. CSV is flat and inspectable; JSON Lines keeps one independently parseable event per line and supports nested content.

Expected generated location: datasets/raw/files/shipment_tracking_events.jsonl inside a batch-controlled extract/output structure.

Grain: one JSON object per carrier tracking event, with nested location/status details.

Dependencies: Generated parent/business keys must correspond to valid source data except for explicitly injected quality-test cases.

Downstream targets: bronze.file_shipment_tracking_events, an entity-specific Silver table or quarantine, and the mapped Gold dimension/fact when applicable.

Action 4.4.FD4 — Inspect and reconcile shipment_tracking_events.jsonl**Application:**

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Inspect and reconcile `shipment_tracking_events.jsonl`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: In VS Code Explorer, expand datasets, then raw, then files only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `shipment_tracking_events.jsonl` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: In VS Code Explorer, expand datasets, then raw, then files only after Phase 5 creates the batch output.
2. LOOK FOR: Locate `shipment_tracking_events.jsonl` under the current batch, not the small sample fixture unless the lesson explicitly requests it.
3. CLICK: Open the file in VS Code as text.
4. LOOK FOR: Inspect the header or first JSON object, delimiters, quoting, date representation, null representation, and line endings.
5. CLICK: Open the batch manifest beside the feed.
6. LOOK FOR: Match the relative path, row or event count, byte size, and checksum entry.
7. DO NOT EDIT: Raw generated output is evidence; correct the generator and create a new batch instead of hand-fixing a raw file.
8. DO NOT CONTINUE UNTIL: The feed structure and manifest entry agree.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

```

What to validate

1. The file exists only after the generator or extractor writes it.
2. The filename extension is not hidden or doubled, such as .csv.txt.
3. CSV headers are unique and match the data dictionary; JSON Lines has exactly one complete object per nonblank line.
4. The manifest count matches an independent count.
5. The SHA-256 checksum matches a fresh calculation.
6. Expected dirty rows remain observable for Silver tests; raw data is not “cleaned” manually.
7. No real customer or employee information is present; the data is fictional.

Git rule

Generated raw batches are normally ignored because they can be recreated and may be large. Small non-sensitive sample fixtures under datasets/sample/ can be tracked for tests. Confirm the rule with `git check-ignore -v` before staging.

Interview-ready explanation

“I treated shipment_tracking_events.jsonl as a source contract with a declared grain, schema, manifest entry, checksum, and downstream mapping. I preserved raw evidence and corrected generation logic rather than editing an output file.”

What your screen should look like now

- The new Phase 4 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 4.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 4.5](#).

Lesson 4.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 4 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Source-system separation

Question:

Where should ERP and digital data live?

Options considered:

- One SQL Server database.
- SQL Server ERP plus PostgreSQL digital.
- Only flat files.

Beginner path selected:

Use SQL Server for ERP and PostgreSQL for digital activity.

Why this path was selected:

Two engines create realistic integration work while remaining manageable locally.

Tradeoff:

More installation, drivers, and dialect handling are required.

What a company might do instead:

A company may use SaaS sources, managed cloud databases, event platforms, and CDC.

How to explain this in an interview:

I separated operational domains across SQL Server and PostgreSQL to demonstrate heterogeneous-source ingestion and dialect-aware engineering.

If you see Result A

The database/schema/table exists and metadata matches the declared columns, keys, and grain. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

The object is absent, already exists with a different definition, or you are connected to the wrong database. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: VS Code, SSMS, pgAdmin, and PowerShell.

Window/panel: Show database tree and column/constraint metadata for representative source tables plus data dictionary.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase04_design-and-create-the-sql-server-and-postgresql-source-_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 4's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 4 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 4.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 4.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Action 4.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Interpret `git status --short`

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 4.5.G4 — Inspect the unstaged diff for `sql/sqlserver/source/01_create_erp_database.sql`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "sql/sqlserver/source/01_create_erp_database.sql"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "sql/sqlserver/source/01_create_erp_database.sql"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the

surrounding explanation; -- is a command option or flag; its exact behavior is defined beside the command; "sql/sqlserver/source/01_create_erp_database.sql" is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Action 4.5.G5 — Stage only the reviewed file sql/sqlserver/source/01_create_erp_database.sql

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "sql/sqlserver/source/01_create_erp_database.sql"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "sql/sqlserver/source/01_create_erp_database.sql"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"sql/sqlserver/source/01_create_erp_database.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Action 4.5.G7 — Create the Phase 4 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: define northstar source schemas"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: define northstar source schemas"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: define northstar source schemas"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Action 4.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

[Back to the Phase 4 lesson index](#)

Action 4.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 4 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: define northstar source schemas` and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 4.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 4 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 4 created the verified boundary described by **Design and create the SQL Server and PostgreSQL source systems**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 4 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

[WRITE YOUR ANSWER]

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 4.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 5 uses each column, constraint, and relationship as a generation requirement.

Phase 4 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

Output independently inspected — [STATUS]

Failure/alternate branch understood — [STATUS]

Screenshot captured and redacted — [STATUS]

Targeted Git commit exists — [STATUS]

Branch pushed and verified on GitHub — [STATUS]

Quiz completed before answer key — [STATUS]

Journal completed — [STATUS]

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 5 — Build and validate the synthetic-data generator

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Complete source schemas and data-quality scenarios.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 6 loads the generated parent and child data into the two database engines.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 5 lesson index

1. [Lesson 5.1 — Understand the phase and starting screen](#)
2. [Lesson 5.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 5.3 — Create and understand the phase files](#)
4. [Lesson 5.4 — Build and validate required objects](#)
5. [Lesson 5.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 5.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** VS Code, VS Code PowerShell terminal, Python virtual environment, and File Explorer.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 5 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 4 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 5 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

VS Code, VS Code PowerShell terminal, Python virtual environment, and File Explorer. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 5 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.

- No new Phase 5 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 5 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 5.1 completion checklist

☐

I read why Phase 5 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 5.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 5 lesson index](#)

Lesson 5.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 5 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A reproducible Python generator that creates all ERP, digital, CSV, and nested JSON source data at configurable scales, keeps normal foreign keys coherent, injects controlled quality defects, writes a batch manifest/checksums, and validates its own output.

2. Why it matters

A portfolio project needs data rich enough to exercise engineering decisions without exposing real people or employer information. A fixed seed and quality fixture turn messy data from random surprise into a repeatable test case.

3. Words to know

Term	Plain-language definition
Module	Python file/package imported or run with <code>python -m</code> .
Function	Named reusable block with inputs and output/side effect.
Loop	Repeats logic over records or tables.
Dictionary	Key/value mapping used for configuration and records.

Term	Plain-language definition
DataFrame	Table-like in-memory data structure from pandas/Spark.
Random seed	Starting value that makes pseudo-random business content reproducible.
Configuration	Values separated from logic, here in YAML and CLI arguments.
Logging	Structured messages about progress and failures.
Exception	Error object raised when code cannot safely continue.
Referential integrity	Child references point to existing parent records for normal data.
Distribution	Pattern of values/likelihoods rather than uniform randomness.
Fixture	Known data/expectation used by tests.
Docstring/type hint	Description and expected Python types that improve readability/tools.

4. What must already be completed

Phases 1–4 complete. `.venv` is active and dependencies installed. Source databases need not contain rows yet.

5. Applications to open

Application	How to open it	Why it is open
VS Code	Repository root; open <code>scripts/data_generation/generate_northstar_data.py</code> .	Read functions, imports, CLI, and TODO work.
Windows PowerShell	Repository root with <code>.venv</code> active.	Run generator/tests and inspect output.
File Explorer or VS Code Explorer	Open <code>datasets/sample/</code> .	Inspect generated files and metadata.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
<code>python -c "import sys, pandas, faker, yaml; print(sys.executable); print(pandas.version)"</code>	Confirms interpreter and core imports.	Avoid debugging generator logic with the wrong Python environment.
<code>python -m scripts.data_generation.generate_northstar_data --scale quick --seed 20260815 --output-dir datasets\generated\practice_quick</code>	Runs generator as a package module with explicit scale, seed, output.	Module execution preserves imports and separates practice output from included sample.
<code>python -m scripts.validation.validate_generated_data --input-dir datasets\generated\practice_quick</code>	Checks required non-empty files and normal source relationships.	Generation success message is not enough.
<code>Get-Content data-sets\generated\practice_quick\metadata\generation_summary.csv</code>	Prints per-file row counts.	You must know what was generated before loading.
<code>python -m pytest -q tests\unit\test_generator.py tests\data_quality\test_sample_quality_fixture.py</code>	Runs deterministic generation and intentional-dirty-data tests.	Proves same seed and expected defects behave as designed.

Python concepts in this generator

- Imports bring in tested libraries instead of rewriting Faker/DataFrame/YAML behavior.
- Functions each generate one subject or perform one responsibility.
- Loops create repeated fictional entities and events.
- Dictionaries represent record fields and table collections.
- DataFrames provide column operations and CSV writing.
- `random.Random(seed)` and `Faker.seed(seed)` make business content repeatable.
- `argparse` gives `--scale`, `--seed`, `--output-dir`, and `--config`.
- Logging says what happened; exceptions stop unsafe output.
- `if __name__ == "__main__":` runs `main()` only when launched, not when imported by tests.

MY TASK

Run quick mode twice with the same seed into two folders, prove selected business files are byte-identical, inspect every controlled issue type, and complete one small generator enhancement with dictionary/test updates.

STARTER SKELETON

```
from __future__ import annotations

import logging
import random
from typing import Any

LOGGER = logging.getLogger(__name__)

def generate_loyalty_points(
    order_total: float,
    loyalty_tier: str,
    rng: random.Random,
) -> int:
    """Return fictional points earned for one valid order."""
    # TODO(USER): define a deterministic base rule.
    base_points = _____
    # TODO(USER): define tier multiplier mapping.
    multiplier_by_tier: dict[str, float] = {_____}
    # TODO(USER): avoid negative points and return int.
    return _____

# TODO(USER): add unit tests for zero, normal, and tier cases.
```

Acceptance criteria: Two same-seed business files match, normal references validate, expected dirty rows are observed, and any enhancement updates code, data dictionary, config if needed, and deterministic tests.

HINT 1 — CONCEPT

Reproducibility applies to business content; batch timestamps are allowed to differ.

HINT 2 — PSEUDOCODE

Generate parents before children and choose IDs from parent DataFrames.

HINT 3 — NEAR-COMPLETE PATTERN

Copy the existing small function/docstring/type-hint style and add tests before scaling.

13. Expected files or output

- 23 generated source files plus four metadata files for quick mode.
- 60 quick customers and 200 quick orders under documented configuration.
- Controlled duplicate, email, quantity, date, reference, currency, order, and timezone issues.
- Passing validation/test output.
- One personally explained small change or documented attempt.

14. How to verify

- Compare selected files with Get-FileHash or pytest same-seed test.
- Open expected fixture and find examples in source CSVs.
- Check order customer IDs all exist.
- Confirm order dates are not before customer signup.
- Confirm no real personal data or real company contact is used.

15. Automated tests

- tests/unit/test_generator.py.
- tests/data_quality/test_sample_quality_fixture.py.
- Standalone generated-data validator.
- Later source row-count reconciliation after load.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
No module named scripts	Script was launched by path from wrong folder/interpreter.	Get-Location; python -c "import sys; print(sys.path[0])".	Run from repository root with python -m scripts.data_generation..	Generator starts.
FileNotFound config	Current folder is not repository root.	Get-Location; Test-Path config\data_generation.yml.	Enter verified root or pass explicit config.	Config loads.
Output differs with same seed	Timestamp fields/batch ID compared or nondeterministic operation added.	Diff selected business CSVs and isolate columns.	Exclude run metadata from reproducibility assertion or seed/sort all business choices.	Business files match.
Generation is slow	Scale too large for debugging.	Read --scale and config.	Use quick; only run portfolio after correctness.	Quick completes and tests pass.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why does generation order matter for foreign keys?
2. Why are realistic distributions better than uniform choices?
3. Why should dirty data be controlled rather than random?
4. What does the main guard do?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What makes two generator runs reproducible?
2. Which file records expected injected issue counts?
3. Why should portfolio scale wait until logic passes quick scale?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture PowerShell showing generator and validation success, plus Explorer showing the four output subfolders and an open manifest. Include the seed/scale, not a password.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Generator read and explained — [STATUS]

☐

Quick run completed — [STATUS]

☐

Same-seed behavior verified — [STATUS]

☐

Normal referential integrity verified — [STATUS]

☐

Controlled issues located — [STATUS]

☐

Tests passed — [STATUS]

☐

Small user-owned task completed — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-5. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-5] (the answer-key section immediately after the quiz in this workbook#phase-5).

Next phase: Phase 6 loads the generated ERP and digital files into the two local source databases.

Required action cards

Action 5.2.1 — Open config/data_generation.yml. Compare quick, small, medium, and portfolio counts. Use quick while debuggi

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open config/data_generation.yml. Compare quick, small, medium, and portfolio counts. Use quick while debuggi. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.

3. Perform only this immediate task: Open `config/data_generation.yml`. Compare quick, small, medium, and portfolio counts. Use quick while debugging.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 1****Action**

Open `config/data_generation.yml`. Compare quick, small, medium, and portfolio counts. Use quick while debugging.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.2.2 — Open the generator. Read imports first: standard library, pandas, YAML, Faker, shared logging.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open the generator. Read imports first: standard library, pandas, YAML, Faker, shared logging. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open the generator. Read imports first: standard library, pandas, YAML, Faker, shared logging.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 2

Action

Open the generator. Read imports first: standard library, pandas, YAML, Faker, shared logging.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.2.3 — Find GenerationContext; explain why seed, scale, output, counts, issues, batch ID, and timestamp travel toge

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Find GenerationContext; explain why seed, scale, output, counts, issues, batch ID, and timestamp travel toge. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Find GenerationContext; explain why seed, scale, output, counts, issues, batch ID, and timestamp travel together.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 3****Action**

Find GenerationContext; explain why seed, scale, output, counts, issues, batch ID, and timestamp travel together.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.2.4 — Trace generation order: reference tables → customers/addresses → orders/items/payments/shipments → inventory →

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Trace generation order: reference tables → customers/addresses → orders/items/payments/shipments → inventory →. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Trace generation order: reference tables → customers/addresses → orders/items/payments/shipments → inventory → digital → files. Parents must exist before children can choose their keys.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 4****Action**

Trace generation order: reference tables → customers/addresses → orders/items/payments/shipments → inventory → digital → files. Parents must exist before children can choose their keys.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.2.5 — Find one weighted choice. Explain why store/online or channel values should not be equally likely by default.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Find one weighted choice. Explain why store/online or channel values should not be equally likely by default. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Find one weighted choice. Explain why store/online or channel values should not be equally likely by default.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 5

Action

Find one weighted choice. Explain why store/online or channel values should not be equally likely by default.

Before continuing

☐

I used the application named in this phase.

Action 5.2.10 — Complete the TODO exercise: add one fictional loyalty_points_balance field to a throwaway branch or add one

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Complete the TODO exercise: add one fictional loyalty_points_balance field to a throwaway branch or add one . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.

3. Perform only this immediate task: Complete the TODO exercise: add one fictional `loyalty_points_balance` field to a throwaway branch or add one generator-only summary metric; update dictionary/tests before merging.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 10****Action**

Complete the TODO exercise: add one fictional `loyalty_points_balance` field to a throwaway branch or add one generator-only summary metric; update dictionary/tests before merging.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -c "import sys, pandas, faker, yaml; print(sys.executable); print(pandas.__version__)"
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -c "import sys, pandas, faker, yaml; print(sys.executable); print(pandas.__version__)"` — `python` invokes Python when that command name is registered; `-c` creates the named branch before switching; `"import sys, pandas, faker, yaml; print(sys.executable); print(pandas.__version__)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.data_generation.generate_northstar_data --scale quick --seed 20260815 --output-dir datasets\generated\practice_quick
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m scripts.data_generation.generate_northstar_data --scale quick --seed 20260815 --output-dir datasets\generated\practice_quick` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.data_generation.generate_northstar_data` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--scale` is a command option or flag; its exact behavior is defined beside the command; `quick` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--seed` is a command option or flag; its exact behavior is defined beside the command; `20260815` is a numeric literal used by the command or expression; `--output` is a command option or flag; its exact behavior is defined beside the command; `-dir` is a command option or flag; its exact behavior is defined beside the command; `datasets` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `generated` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `practice_quick` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.2.C3 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.validation.validate_generated_data --input-dir datasets\generated\practice_quick
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m scripts.validation.validate_generated_data --input-dir datasets\generated\practice_quick` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.validation.validate_generated_data` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--input` is a command option or flag; its exact behavior is

defined beside the command; `-dir` is a command option or flag; its exact behavior is defined beside the command; `datasets` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `generated` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `practice_quick` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

Action 5.2.C4 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Content datasets\generated\practice_quick\metadata\generation_summary.csv
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-Content datasets\generated\practice_quick\metadata\generation_summary.csv — Get-Content is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; datasets is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; generated is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; practice_quick is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; metadata is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; generation_summary.csv is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

[Back to the Phase 5 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 5.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 5 starting-screen checklist and re-verify the active context.

Lesson 5.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 5 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — config/

Exact folder name: config

Exact parent: repository root

Why it is needed now: Phase 5 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: config.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 5.D1.1 — Create the folder config

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\config" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\config" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\config" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\config" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\config" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\config" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — scripts/

Exact folder name: `scripts`

Exact parent: `repository root`

Why it is needed now: Phase 5 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: scripts.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 5.D2.1 — Create the folder scripts

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name,

keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\scripts" -PathType Container` and require True.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\scripts" -PathType Container`.

2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — tests/

Exact folder name: tests

Exact parent: repository root

Why it is needed now: Phase 5 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: tests.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 5.D3.1 — Create the folder tests

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\tests" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\tests" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\tests"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\tests" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\tests" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\tests" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — `scripts/data_generation/`

Exact folder name: `data_generation`

Exact parent: `scripts`

Why it is needed now: Phase 5 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `scripts` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `data_generation`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 5.D4.1 — Create the folder `scripts/data_generation`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The `User` segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\tests\unit" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\tests\unit" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run Test-Path ".\tests\unit" -PathType Container.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — config/data_generation.yml

Exact filename: data_generation.yml

Filename extension: .yml. In this project it identifies human-readable configuration and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: config relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: human-readable configuration for Phase 5.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? Yes—review carefully before Git staging.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in config one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: data_generation.yml.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled data_generation.yml and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 5.F1.1 — Create the file config/data_generation.yml from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\config\data_generation.yml" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\config\data_generation.yml" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\config\data_generation.yml" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\config\data_generation.yml" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "config/data_generation.yml"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `config`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `config/data_generation.yml`.
3. In PowerShell at the repository root, run `Test-Path ".\config\data_generation.yml"` and require True.
4. Run `git status --short -- "config/data_generation.yml"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for config/data_generation.yml

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: YAML

Exact file: `config/data_generation.yml`

Purpose: human-readable configuration.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 5.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

[Back to the Phase 5 lesson index](#)

File introduction — `scripts/data_generation/generate_northstar_data.py`

Exact filename: `generate_northstar_data.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/data_generation` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 5.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `scripts/data_generation` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `generate_northstar_data.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `generate_northstar_data.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 5.F2.1 — Create the file `scripts/data_generation/generate_northstar_data.py` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\data_generation\generate_northstar_data.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\scripts\data_generation\generate_northstar_data.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts\data_generation\generate_northstar_data.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\scripts\data_generation\generate_northstar_data.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/data_generation/generate_northstar_data.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/data_generation`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/data_generation/generate_northstar_data.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\data_generation\generate_northstar_data.py" and require True.`
4. Run `git status --short -- "scripts/data_generation/generate_northstar_data.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `scripts/data_generation/generate_northstar_data.py`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/data_generation/generate_northstar_data.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 5.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

[Back to the Phase 5 lesson index](#)

File introduction — `scripts/validation/validate_generated_data.py`

Exact filename: `validate_generated_data.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/validation` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 5.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `scripts/validation` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `validate_generated_data.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `validate_generated_data.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 5.F3.1 — Create the file `scripts/validation/validate_generated_data.py` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\validation\validate_generated_data.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\scripts\validation\validate_generated_data.py" -ErrorAction Stop`
— `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts\validation\validate_generated_data.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\scripts\validation\validate_generated_data.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/validation/validate_generated_data.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/validation`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/validation/validate_generated_data.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\validation\validate_generated_data.py"` and require `True`.
4. Run `git status --short -- "scripts/validation/validate_generated_data.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `scripts/validation/validate_generated_data.py`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/validation/validate_generated_data.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 5.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

"""Validate generated files without requiring SQL Server, PostgreSQL, or Databricks."""
from __future__ import annotations

import argparse
import json
from pathlib import Path

import pandas as pd

def main() -> None:
    parser = argparse.ArgumentParser()
    parser.add_argument("--input-dir", type=Path, default=Path("datasets/sample"))
    args = parser.parse_args()
    customer = pd.read_csv(args.input_dir / "sqlserver/customers.csv")
    orders = pd.read_csv(args.input_dir / "sqlserver/orders.csv")

File introduction — tests/unit/test_generator.py

Exact filename: test_generator.py

Filename extension: .py. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: tests/unit relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 5.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in tests/unit one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: test_generator.py.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled test_generator.py and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 5.F4.1 — Create the file tests/unit/test_generator.py from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\tests\unit\test_generator.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\tests\unit\test_generator.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\tests\unit\test_generator.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\tests\unit\test_generator.py" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "tests/unit/test_generator.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `tests/unit`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `tests/unit/test_generator.py`.
3. In PowerShell at the repository root, run `Test-Path ".\tests\unit\test_generator.py"` and require True.
4. Run `git status --short -- "tests/unit/test_generator.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for tests/unit/test_generator.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `tests/unit/test_generator.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 5.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
from __future__ import annotations

import json
import subprocess
import sys
from pathlib import Path

import pandas as pd

def run_generator(output: Path) -> None:
    subprocess.run([
        sys.executable, "-m", "scripts.data_generation.generate_northstar_data",
        "--scale", "quick", "--seed", "20260815", "--output-dir", str(output),
    ], check=True)

def test_quick_generator_counts_and_integrity(tmp_path: Path) -> None:
    output = tmp_path / "generated"
    run_generator(output)
    customers = pd.read_csv(output / "sqlserver/customers.csv")
```

```

orders = pd.read_csv(output / "sqlserver/orders.csv")
items = pd.read_csv(output / "sqlserver/order_items.csv")

[Back to the Phase 5 lesson index](#)

What your screen should look like now

- Every Phase 5 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 5.3 completion checklist

☐

`config/data_generation.yml` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`scripts/data_generation/generate_northstar_data.py` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`scripts/validation/validate_generated_data.py` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`tests/unit/test_generator.py` was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 5.4](#) and recheck the root and branch.

Lesson 5.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 5.4.G1 — Inspect the current state without changing it

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.4.G2 — Create the smallest required object or decision

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Create the smallest required object or decision. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.

4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.4.G3 — Run the phase-specific verification

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run the phase-specific verification. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.4.G4 — Demonstrate one safe failure or alternate-result branch

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 5 lesson index](#)

Action 5.4.G5 — Record evidence and prepare the downstream handoff

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

What your screen should look like now

- The new Phase 5 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 5.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 5.5](#).

Lesson 5.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 5 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Deterministic synthetic data

Question:

How can fake data be realistic yet reproducible?

Options considered:

- Unseeded random generation.
- Deterministic seeded generation with configuration.
- Manually typed fixtures only.

Beginner path selected:

Use seeded Faker/pandas generation plus controlled dirty-data injection.

Why this path was selected:

Reruns can be compared, tests know the expected defects, and volumes can be configured.

Tradeoff:

Synthetic distributions do not prove production behavior.

What a company might do instead:

Companies use masked production-like data, governed test-data management, and privacy review.

How to explain this in an interview:

I used deterministic seeds and an expected-quality-issue manifest so the same defects could test Bronze/Silver behavior repeatedly.

Design decision — Python scripts versus notebooks

Question:

Should synthetic-data generation and local loading be built as reusable Python scripts or interactive notebooks?

Options considered:

- Versioned .py scripts with configuration and command-line arguments.
- Jupyter notebooks.
- Manual spreadsheet generation.

Beginner path selected:

Use Python scripts for local generation, loading, extraction, validation, and repeatable command-line execution; use Databricks notebooks only where the remote platform requires them.

Why this path was selected:

Scripts are easier to test, parameterize, review, run non-interactively, and reuse in CI. The learner still sees each section assembled and explained before the full script.

Tradeoff:

Scripts provide less immediate visual exploration than notebooks and require deliberate logging and small tests.

What a company might do instead:

A company may package Python modules, use workflow frameworks, containerize execution, and reserve notebooks for exploration or platform-specific tasks.

How to explain this in an interview:

I chose scripts for reproducible local engineering workflows and notebooks for Databricks execution, separating exploratory convenience from production-style testability.

If you see Result A

Generation completes with deterministic business content, expected counts, and intentional defect totals. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

Counts or checksums differ because configuration, seed, package version, or generation order changed. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: VS Code, VS Code PowerShell terminal, Python virtual environment, and File Explorer.

Window/panel: Show generator logs, summary counts, validation results, and controlled dirty-data manifest.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase05_build-and-validate-the-synthetic-data-generator_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 5's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 5 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 5.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 5.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Interpret git status --short

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 5.5.G4 — Inspect the unstaged diff for config/data_generation.yml

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "config/data_generation.yml"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** git diff -- "config/data_generation.yml" — git calls the Git version-control program; diff is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -- is a command option or flag; its exact behavior is defined beside the command; "config/data_generation.yml" is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.5.G5 — Stage only the reviewed file `config/data_generation.yml`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "config/data_generation.yml"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "config/data_generation.yml"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"config/data_generation.yml"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 5.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.5.G7 — Create the Phase 5 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: build deterministic synthetic data generator"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: build deterministic synthetic data generator"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: build deterministic synthetic data generator"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Action 5.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 5 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: build deterministic synthetic data generator and the intended changed paths`.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 5.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 5 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 5 created the verified boundary described by **Build and validate the synthetic-data generator**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 5 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 5.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 6 loads the generated parent and child data into the two database engines.

Phase 5 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

Output independently inspected — [STATUS]

Failure/alternate branch understood — [STATUS]

Screenshot captured and redacted — [STATUS]

Targeted Git commit exists — [STATUS]

Branch pushed and verified on GitHub — [STATUS]

Quiz completed before answer key — [STATUS]

Journal completed — [STATUS]

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 6 — Load and verify the local source databases

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Generated files plus empty, verified source schemas.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 7 reads the populated sources into traceable extraction batches.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 6 lesson index

1. [Lesson 6.1 — Understand the phase and starting screen](#)
2. [Lesson 6.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 6.3 — Create and understand the phase files](#)
4. [Lesson 6.4 — Build and validate required objects](#)
5. [Lesson 6.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 6.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** VS Code, PowerShell, SSMS, pgAdmin, SQL Server, and PostgreSQL.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 6 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 5 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 6 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

VS Code, PowerShell, SSMS, pgAdmin, SQL Server, and PostgreSQL. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 6 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.

- No new Phase 6 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 6 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 6.1 completion checklist

☐

I read why Phase 6 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 6.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 6 lesson index](#)

Lesson 6.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 6 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

Repeatable local source-loading processes using secret-free configuration. The beginner path uses pandas/SQLAlchemy in dependency order; the scalable path introduces SQL Server bulk copy and PostgreSQL COPY concepts. Row counts, transactions, failures, and duplicate-run behavior are recorded.

2. Why it matters

Generated files are not database sources until rows are loaded and reconciled. Loading teaches drivers, connection strings, environment variables, transaction scope, dependency order, bulk tradeoffs, and why rerunning append logic without a batch strategy can duplicate data.

3. Words to know

Term	Plain-language definition
Connection string	Structured host/database/auth/driver information.
Environment variable	Configuration value read at runtime; secrets stay outside code.
Transaction	All-or-nothing group of database changes.

Term	Plain-language definition
Commit / rollback	Make transaction permanent or undo it.
Chunk	Subset of rows loaded at a time.
Bulk load	Database-optimized high-throughput ingestion such as bcp or COPY.
Dependency order	Parent tables loaded before child foreign keys.
Duplicate-run protection	Rule preventing repeated input from creating duplicate trusted rows.
Trusted connection	SQL Server Windows authentication from the current identity.
Row-count reconciliation	Generated count compared to database count and inserted delta.
Retry	Repeat a transient operation under limits.
Staging	Temporary landing table used before validation/merge.

4. What must already be completed

Source tables exist; quick data validates; .env, ODBC, psycopg, SQLAlchemy are installed. You know your local SQL Server instance and PostgreSQL credentials privately.

5. Applications to open

Application	How to open it	Why it is open
VS Code	Repository root; open .env.example and loader scripts.	Create private .env and read load order.
Windows PowerShell	Repository root with .env active.	Run loaders and config checks.
SSMS	Connected to NorthstarRetail_ERP.	Validate ERP counts and dirty fixtures.
pgAdmin or psql	Connected to northstar_digital.	Validate digital counts.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
Copy-Item .env.example .env	Creates a private local configuration copy.	Code needs environment-specific values without changing a public template.
git check-ignore .env	Asks Git whether .env is ignored.	Secrets must not be tracked.
python -c "from scripts.utilities.config import load_environment; load_environment(); import os; print(os.getenv('SQLSERVER_HOST')); print(os.getenv('POSTGRES_HOST'))"	Loads config and prints only non-secret hosts.	Confirms .env parsing without displaying passwords.
python -m scripts.loading.load_sqlserver_source --input-dir datasets/sample/sqlserver --mode replace-dev	Loads ERP CSVs in dependency order into SQL Server.	Source tables must contain data before extraction.

Line or action	Meaning	Why it belongs here
python -m scripts.loading.load_postgres_source --input-dir datasets\sample\postgres --mode replace-dev	Loads digital CSVs in dependency order into PostgreSQL.	Digital source needs separate driver/dialect path.
-- Execute sql/sqlserver/validation/01_validate_erp_source.sql	Shows counts, orphans, malformed emails, impossible quantities, duplicate business keys.	A successful loader process does not prove correct population.
-- Execute sql/postgres/validation/01_validate_digital_source.sql	Shows counts, orphan events, out-of-order events, and conversion overview.	Verifies digital load and intentional event issue.

Beginner versus bulk loading

Method	Best now	Benefit	Cost/risk
pandas + SQLAlchemy	learning/small fixtures	readable, same language, logs, transactions	slower, type inference needs care
SQL Server bcp/BULK INSERT	larger local files	high throughput	path permissions, mapping, error files, transaction design
PostgreSQL COPY\copy	larger CSV	optimized server/client loading	quoting/types/error handling and client/server path distinction

Do not label the simple method 'bad'. It is appropriate for a small learning batch; the decision changes with volume and operating requirements.

MY TASK

Load both sources, reconcile every generated file count to its database table, then design (do not blindly implement) a checksum-based duplicate-run guard and a bulk-load migration plan.

STARTER SKELETON

```
def already_loaded(connection, source_checksum: str) -> bool:
    """Return True when this exact generated input was committed before."""
    # TODO(USER): query audit.source_load_batch or a child file table.
    result = connection.execute(_____, {"checksum": source_checksum})
    return _____

def record_success(connection, batch_id: str, checksum: str, rows: int) -> None:
    # TODO(USER): insert audit record inside the same transaction.
    _____
```

Acceptance criteria: Both databases match generated counts, normal FK checks pass, controlled dirty rows remain available for Silver, .env is untracked, and duplicate-run/bulk strategy is documented.

HINT 1 — CONCEPT

Load parents before children and keep explicit table order.

HINT 2 — PSEUDOCODE

A primary-key failure is safer than silent duplication, but not a complete operational rerun strategy.

HINT 3 — NEAR-COMPLETE PATTERN

Record checksum and success in the same transaction as data changes so they cannot disagree.

13. Expected files or output

- Populated ERP and digital source tables.
- Loader logs with row counts.
- Source validation result evidence.
- Private .env, ignored.
- Duplicate-run and bulk-load decision notes.

14. How to verify

- Generated summary count equals table count for each source.
- No FK orphans.
- Known invalid quantities/emails/events remain observable.
- A failed test transaction does not leave unexplained partial rows.
- `git status` never lists `.env`.

15. Automated tests

- Source validation SQL.
- Manual generated-to-source count matrix.
- Integration test can be added when local DBs are available; CI remains infrastructure-free.
- Secret scanner and ignored-file check.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
pyodbc driver error	Exact driver/server/auth mismatch.	pyodbc driver list and SQL Server context in SSMS.	Copy exact driver name/verified host to <code>.env</code> ; use intended auth.	Python <code>SELECT 1</code> succeeds.
FK constraint failure	Load order or source file mismatch.	Read table/key in exception; query parent ID.	Do not disable constraint; correct generation/order/input.	Transaction rerun passes.
PostgreSQL password failed	Wrong private credential/user/database.	Test <code>psql</code> with same host/port/user/database.	Correct <code>.env</code> after authorized reset; never print password.	Loader connects.
Primary key violation on re-run	Append repeated same IDs.	Check before counts and input checksum.	Use <code>replace-dev</code> in disposable setup or implement guarded batch merge.	Counts equal one batch.
Partial source load	Transaction boundary or DDL/autocommit issue.	Inspect counts/audit/status after error.	Rollback/reset only disposable data, fix cause, reload in one controlled transaction.	All tables reconcile.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why do environment variables improve security but not automatically guarantee it?
2. Why are table load order and transaction scope different concerns?
3. When is pandas loading appropriate?
4. What should a duplicate-run guard record?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which file should contain your real local password?
2. Why should a child table not load before its parent?
3. What is one advantage and one risk of bulk loading?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture loader log counts and SSMS/pgAdmin validation result grids. Crop `.env` and connection dialogs containing secrets. Save the image under `docs/images/` with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: load and reconcile synthetic source databases
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Private config created/ignored — [STATUS]

☐

SQL Server load reconciled — [STATUS]

☐

PostgreSQL load reconciled — [STATUS]

☐

Controlled issues preserved — [STATUS]

☐

Transaction behavior understood — [STATUS]

☐

Duplicate-run plan documented — [STATUS]

☐

Bulk alternatives explained — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-6. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-6] (the answer-key section immediately after the quiz in this workbook#phase-6).

Next phase: Phase 7 extracts a timestamped, manifest-driven batch for the local-first Databricks handoff.

Required action cards

Action 6.2.1 — Copy `.env.example` to `.env`; never edit the example with real secrets. Confirm `.env` is ignored before typi

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Copy `.env.example` to `.env`; never edit the example with real secrets. Confirm `.env` is ignored before typi. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Copy `.env.example` to `.env`; never edit the example with real secrets. Confirm `.env` is ignored before typing credentials.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 1****Action**

Copy `.env.example` to `.env`; never edit the example with real secrets. Confirm `.env` is ignored before typing credentials.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.2 — Set SQLSERVER_HOST to the verified server name; use trusted connection for local Windows authentication when

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Set SQLSERVER_HOST to the verified server name; use trusted connection for local Windows authentication when. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Set SQLSERVER_HOST to the verified server name; use trusted connection for local Windows authentication when configured. Set exact ODBC driver name.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 2

Action

Set SQLSERVER_HOST to the verified server name; use trusted connection for local Windows authentication when configured. Set exact ODBC driver name.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.3 — Set PostgreSQL host, port, database, username, and private password in .env.

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Set PostgreSQL host, port, database, username, and private password in .env. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Set PostgreSQL host, port, database, username, and private password in .env.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.

6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

pgAdmin 4 or PostgreSQL `psql`, as named in the action. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

Set PostgreSQL host, port, database, username, and private password in `.env`.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.4 — Open each loader and inspect TABLE_ORDER. Parent tables must precede products/orders/items/events.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Open each loader and inspect TABLE_ORDER. Parent tables must precede products/orders/items/events. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open each loader and inspect TABLE_ORDER. Parent tables must precede products/orders/items/events.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 4

Action

Open each loader and inspect TABLE_ORDER. Parent tables must precede products/orders/items/events.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

Action 6.2.6 — Run SQL Server loader. It uses one transaction and logs before/inserted/after counts. If a child fails, transa

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run SQL Server loader. It uses one transaction and logs before/inserted/after counts. If a child fails, transa. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Run SQL Server loader. It uses one transaction and logs before/inserted/after counts. If a child fails, transaction behavior should prevent a partial commit within the connection scope.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 6****Action**

Run SQL Server loader. It uses one transaction and logs before/inserted/after counts. If a child fails, transaction behavior should prevent a partial commit within the connection scope.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

Action 6.2.8 — Run source validation SQL in SSMS and pgAdmin. Controlled invalid business values should be visible; database

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run source validation SQL in SSMS and pgAdmin. Controlled invalid business values should be visible; database . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Run source validation SQL in SSMS and pgAdmin. Controlled invalid business values should be visible; database foreign-key violations should be zero.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 8****Action**

Run source validation SQL in SSMS and pgAdmin. Controlled invalid business values should be visible; database foreign-key violations should be zero.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.9 — Record generated versus loaded counts. If you rerun append mode, primary keys should fail rather than silently

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Record generated versus loaded counts. If you rerun append mode, primary keys should fail rather than silently. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Record generated versus loaded counts. If you rerun append mode, primary keys should fail rather than silently duplicate; this is a signal that source-load batch protection needs design.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 9

Action

Record generated versus loaded counts. If you rerun append mode, primary keys should fail rather than silently duplicate; this is a signal that source-load batch protection needs design.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.10 — Study scalable options: SQL Server bcp/BULK INSERT and PostgreSQL \copy/COPY. Do not switch until the simp

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Study scalable options: SQL Server bcp/BULK INSERT and PostgreSQL \copy/COPY. Do not switch until the simp. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Study scalable options: SQL Server bcp/BULK INSERT and PostgreSQL \copy/COPY. Do not switch until the simple path works and you can preserve transactions, mappings, and logs.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 10****Action**

Study scalable options: SQL Server bcp/BULK INSERT and PostgreSQL \copy/COPY. Do not switch until the simple path works and you can preserve transactions, mappings, and logs.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.11 — Complete TODO: add an explicit load batch record or file checksum guard before supporting routine append rerun

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Complete TODO: add an explicit load batch record or file checksum guard before supporting routine append rerun. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Complete TODO: add an explicit load batch record or file checksum guard before supporting routine append reruns.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 11

Action

Complete TODO: add an explicit load batch record or file checksum guard before supporting routine append reruns.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

I can describe what changed on the screen or filesystem.

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Copy-Item .env.example .env
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `Copy-Item .env.example .env` — `Copy-Item` copies a selected file or folder; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `env.example` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `env` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
git check-ignore .env
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git check-ignore .env` — `git` calls the Git version-control program; `check-ignore` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `env` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.2.C3 — Windows PowerShell

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -c "from scripts.utilities.config import load_environment; load_environment(); import os; print(os.getenv('SQLSERVER_HOST')); print(os.getenv('POSTGRES_HOST'))"
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -c "from scripts.utilities.config import load_environment; load_environment(); import os; print(os.getenv('SQLSERVER_HOST')); print(os.getenv('POSTGRES_HOST'))"` — python invokes Python when that command name is registered; `-c` creates the named branch before switching; `"from scripts.utilities.config import load_environment; load_environment(); import os; print(os.getenv('SQLSERVER_HOST')); print(os.getenv('POSTGRES_HOST'))"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

[Back to the Phase 6 lesson index](#)

Action 6.2.C5 — Windows PowerShell

Application:

pgAdmin 4 or PostgreSQL `psql`, as named in the action

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.loading.load_postgres_source --input-dir datasets\sample\postgres --mode replace-dev
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m scripts.loading.load_postgres_source --input-dir datasets\sample\postgres --mode replace-dev` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.loading.load_postgres_source` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--input` is a command option or flag; its exact behavior is defined beside the command; `-dir` is a command option or flag; its exact behavior is defined beside the command; `datasets` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `sample` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `postgres` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--mode` is a command option or flag; its exact behavior is defined beside the command; `replace-dev` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.2.C6 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
-- Execute sql/sqlserver/validation/01_validate_erp_source.sql
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** -- Execute sql/sqlserver/validation/01_validate_erp_source.sql is a comment for a human reader; it normally does not change data or execute business logic.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 6.2.C7 — pgAdmin Query Tool

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:
pgAdmin Query Tool

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
-- Execute sql/postgres/validation/01_validate_digital_source.sql
```

Where to enter it:

pgAdmin Query Tool. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** -- Execute sql/postgres/validation/01_validate_digital_source.sql is a comment for a human reader; it normally does not change data or execute business logic.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 6.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 6 starting-screen checklist and re-verify the active context.

Lesson 6.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 6 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — scripts/

Exact folder name: `scripts`

Exact parent: `repository root`

Why it is needed now: Phase 6 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `scripts`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 6.D1.1 — Create the folder scripts

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\scripts" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run Test-Path ".\scripts" -PathType Container.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/

Exact folder name: sql

Exact parent: repository root

Why it is needed now: Phase 6 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: sql.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 6.D2.1 — Create the folder sql

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\scripts\loading" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/postgres/

Exact folder name: postgres

Exact parent: sql

Why it is needed now: Phase 6 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `sql` one level at a time.

4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: postgres.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 6.D4.1 — Create the folder sql/postgres

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\sql\postgres" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\sql\postgres" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\sql\postgres" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql\postgres" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\postgres" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\postgres" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/sqlserver/

Exact folder name: sqlserver

Exact parent: sql

Why it is needed now: Phase 6 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path sql one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: sqlserver.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 6.D5.1 — Create the folder sql/sqlserver

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\sql\sqlserver\validation" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\sqlserver\validation" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\sqlserver\validation" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — .env.example

Exact filename: `.env.example`

Filename extension: `.example`. In this project it identifies project text or configuration and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `.` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project text or configuration for Phase 6.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? Yes—review carefully before Git staging.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in . one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: .env.example.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled .env.example and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 6.F1.1 — Create the file .env.example from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\env.example" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\env.example" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\env.example"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\env.example" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- ".env.example"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `..`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `.env.example`.
3. In PowerShell at the repository root, run `Test-Path ".\env.example"` and require `True`.
4. Run `git status --short -- ".env.example"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for .env.example

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: configuration text

Exact file: `.env.example`

Purpose: project text or configuration.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 6.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Copy this file to .env. Never commit .env.
# Track A uses Windows Authentication for SQL Server by default.

APP_ENV=dev

File introduction — scripts/loading/load_sqlserver_source.py

Exact filename: load_sqlserver_source.py

Filename extension: .py. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: scripts/loading relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 6.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in scripts/loading one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: load_sqlserver_source.py.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled load_sqlserver_source.py and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 6.F2.1 — Create the file scripts/loading/load_sqlserver_source.py from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.

3. **CLICK:** Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. **TYPE THIS:** Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. **PRESS:** Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. **LOOK FOR:** Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. **DO NOT CONTINUE UNTIL:** Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\loading\load_sqlserver_source.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\scripts\loading\load_sqlserver_source.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts\loading\load_sqlserver_source.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\scripts\loading\load_sqlserver_source.py" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/loading/load_sqlserver_source.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/loading`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/loading/load_sqlserver_source.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\loading\load_sqlserver_source.py"` and require True.
4. Run `git status --short -- "scripts/loading/load_sqlserver_source.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `scripts/loading/load_sqlserver_source.py`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/loading/load_sqlserver_source.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 6.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

[Back to the Phase 6 lesson index](#)

File introduction — `scripts/loading/load_postgres_source.py`

Exact filename: `load_postgres_source.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/loading` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 6.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `scripts/loading` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `load_postgres_source.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `load_postgres_source.py` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 6.F3.1 — Create the file `scripts/loading/load_postgres_source.py` from PowerShell

Application:

pgAdmin 4 or PostgreSQL `psql`, as named in the action

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\loading\load_postgres_source.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\scripts\loading\load_postgres_source.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts\loading\load_postgres_source.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\scripts\loading\load_postgres_source.py" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/loading/load_postgres_source.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/loading`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/loading/load_postgres_source.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\loading\load_postgres_source.py"` and require True.
4. Run `git status --short -- "scripts/loading/load_postgres_source.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for scripts/loading/load_postgres_source.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/loading/load_postgres_source.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 6.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
"""Load generated digital CSVs into local PostgreSQL."""
from __future__ import annotations

import argparse
import logging
from pathlib import Path
```

```

import pandas as pd
from sqlalchemy import text

from scripts.utilities.config import load_environment
from scripts.utilities.database import postgres_engine
from scripts.utilities.logging_utils import configure_logging

LOGGER = logging.getLogger("northstar.load_postgres")
TABLE_ORDER = ["web_users", "campaigns", "web_sessions", "web_events", "campaign_touchpoints", "marketing_spend"]

def main() -> None:
    parser = argparse.ArgumentParser()
    parser.add_argument("--input-dir", type=Path, default=Path("datasets/sample/postgres"))
    parser.add_argument("--mode", choices=["append", "replace-dev"], default="append")
    args = parser.parse_args()
    configure_logging(); load_environment()

[Back to the Phase 6 lesson index](#)

File introduction — sql/sqlserver/validation/01_validate_erp_source.sql

Exact filename: 01_validate_erp_source.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/sqlserver/validation relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 6.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/sqlserver/validation one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 01_validate_erp_source.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 01_validate_erp_source.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 6.F4.1 — Create the file sql/sqlserver/validation/01_validate_erp_source.sql from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\validation\01_validate_erp_source.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\validation\01_validate_erp_source.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\validation\01_validate_erp_source.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\sqlserver\validation\01_validate_erp_source.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add -Force, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/validation/01_validate_erp_source.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/validation`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/validation/01_validate_erp_source.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\validation\01_validate_erp_source.sql"` and require True.
4. Run `git status --short -- "sql/sqlserver/validation/01_validate_erp_source.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/validation/01_validate_erp_source.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/validation/01_validate_erp_source.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 6.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: SQL Server / T-SQL
-- Run in: SSMS, NorthstarRetail_ERP.
USE NorthstarRetail_ERP;
GO

-- Row counts. Replace expected values with the generation summary for your chosen scale.
SELECT 'customers' AS table_name, COUNT_BIG(*) AS row_count FROM erp.customers
UNION ALL SELECT 'orders', COUNT_BIG(*) FROM erp.orders
UNION ALL SELECT 'order_items', COUNT_BIG(*) FROM erp.order_items
UNION ALL SELECT 'products', COUNT_BIG(*) FROM erp.products
UNION ALL SELECT 'shipments', COUNT_BIG(*) FROM erp.shipments;

-- Referential integrity checks should return zero because source foreign keys are enabled.
SELECT COUNT_BIG(*) AS orphan_order_customers
FROM erp.orders AS o
LEFT JOIN erp.customers AS c ON c.customer_id = o.customer_id
WHERE c.customer_id IS NULL;

SELECT COUNT_BIG(*) AS orphan_order_items
FROM erp.order_items AS oi
LEFT JOIN erp.orders AS o ON o.order_id = oi.order_id
WHERE o.order_id IS NULL;

-- Controlled dirty-data observations; nonzero values are expected in the learning dataset.
SELECT COUNT_BIG(*) AS null_or_malformed_emails
FROM erp.customers
WHERE email IS NULL OR email NOT LIKE '%@%_%';

SELECT COUNT_BIG(*) AS impossible_quantities
FROM erp.order_items
WHERE quantity <= 0;

SELECT customer_number, COUNT_BIG(*) AS duplicate_count
FROM erp.customers
```

```
GROUP BY customer_number
HAVING COUNT_BIG(*) > 1;
```

[Back to the Phase 6 lesson index](#)

File introduction — sql/postgres/validation/01_validate_digital_source.sql

Exact filename: 01_validate_digital_source.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/postgres/validation relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 6.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/postgres/validation one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 01_validate_digital_source.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 01_validate_digital_source.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 6.F5.1 — Create the file sql/postgres/validation/01_validate_digital_source.sql from PowerShell

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\postgres\validation\01_validate_digital_source.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\postgres\validation\01_validate_digital_source.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\postgres\validation\01_validate_digital_source.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\postgres\validation\01_validate_digital_source.sql" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/postgres/validation/01_validate_digital_source.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/postgres/validation`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/postgres/validation/01_validate_digital_source.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\postgres\validation\01_validate_digital_source.sql"` and require True.
4. Run `git status --short -- "sql/postgres/validation/01_validate_digital_source.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/postgres/validation/01_validate_digital_source.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/postgres/validation/01_validate_digital_source.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 6.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: PostgreSQL SQL
-- Run in: pgAdmin Query Tool connected to northstar_digital.
SELECT 'web_users' AS table_name, COUNT(*) AS row_count FROM digital.web_users
UNION ALL SELECT 'web_sessions', COUNT(*) FROM digital.web_sessions
UNION ALL SELECT 'web_events', COUNT(*) FROM digital.web_events
```

```

UNION ALL SELECT 'campaigns', COUNT(*) FROM digital.campaigns
UNION ALL SELECT 'marketing_spend', COUNT(*) FROM digital.marketing_spend;

SELECT COUNT(*) AS orphan_events
FROM digital.web_events AS e
LEFT JOIN digital.web_sessions AS s ON s.session_id = e.session_id
WHERE s.session_id IS NULL;

SELECT COUNT(*) AS out_of_order_events
FROM digital.web_events AS e
JOIN digital.web_sessions AS s ON s.session_id = e.session_id
WHERE e.event_timestamp < s.session_start_utc;

SELECT source_channel, COUNT(*) AS sessions, COUNT(converted_order_id) AS converted_sessions
FROM digital.web_sessions
GROUP BY source_channel
ORDER BY sessions DESC;

```

Line-by-line explanation

- **Line 1:** -- Dialect: PostgreSQL SQL is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** -- Run in: pgAdmin Query Tool connected to northstar_digital. is a comment for a human reader; it normally does not change data or execute business logic.

What your screen should look like now

- Every Phase 6 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 6.3 completion checklist

☐

`.env.example` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`scripts/loading/load_sqlserver_source.py` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`scripts/loading/load_postgres_source.py` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`sql/sqlserver/validation/01_validate_erp_source.sql` was created by me, saved, located correctly, and inspected — [STATUS]

☐

`sql/postgres/validation/01_validate_digital_source.sql` was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 6.4](#) and recheck the root and branch.

Lesson 6.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 6.4.G1 — Inspect the current state without changing it

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.4.G2 — Create the smallest required object or decision

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create the smallest required object or decision. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.

4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.4.G3 — Run the phase-specific verification

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run the phase-specific verification. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.4.G4 — Demonstrate one safe failure or alternate-result branch

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 6 lesson index](#)

Action 6.4.G5 — Record evidence and prepare the downstream handoff

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

What your screen should look like now

- The new Phase 6 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 6.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 6.5](#).

Lesson 6.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 6 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Verification before automation

Question:

Should the phase prioritize a visible manual verification or jump directly to automation?

Options considered:

- Manual verification first, then automation.
- Automation without a known-good baseline.
- Manual operation forever.

Beginner path selected:

Establish one verified manual baseline and then automate repeatable checks.

Why this path was selected:

A known-good example makes failures interpretable and prevents automation from hiding a wrong assumption.

Tradeoff:

The first run takes longer.

What a company might do instead:

Teams often pair infrastructure as code and automated tests with controlled bootstrap and acceptance procedures.

How to explain this in an interview:

I established a verified baseline, then encoded the same contract in tests and orchestration so automation preserved meaning rather than just speed.

If you see Result A

Loaded table counts match generated counts and foreign-key checks pass. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

A table is empty, partially loaded, duplicated, or has rejected/constraint-failing rows. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: VS Code, PowerShell, SSMS, pgAdmin, SQL Server, and PostgreSQL.

Window/panel: Show SSMS/pgAdmin row counts and loader audit results.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase06_load-and-verify-the-local-source-databases_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 6's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 6 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 6.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Interpret git status --short

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 6.5.G4 — Inspect the unstaged diff for .env.example

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- ".env.example"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- ".env.example"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `".env.example"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.5.G5 — Stage only the reviewed file `.env.example`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- ".env.example"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- ".env.example"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `".env.example"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 6.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.5.G7 — Create the Phase 6 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: load and validate local source databases"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: load and validate local source databases"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: load and validate local source databases"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Action 6.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 6 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message feat: load and validate local source databases and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 6.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 6 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 6 created the verified boundary described by **Load and verify the local source databases**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 6 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 6.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 7 reads the populated sources into traceable extraction batches.

Phase 6 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 7 — Build full and incremental local extraction

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Populated sources and reproducible full/incremental extract logic.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 8 creates the cloud landing location that receives those local batches.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 7 lesson index

1. [Lesson 7.1 — Understand the phase and starting screen](#)
2. [Lesson 7.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 7.3 — Create and understand the phase files](#)
4. [Lesson 7.4 — Build and validate required objects](#)
5. [Lesson 7.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 7.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** VS Code, PowerShell, SSMS, pgAdmin, Python, and File Explorer.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 7 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 6 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 7 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

VS Code, PowerShell, SSMS, pgAdmin, Python, and File Explorer. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 7 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 7 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 7 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 7.1 completion checklist

☐

I read why Phase 7 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 7.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 7 lesson index](#)

Lesson 7.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 7 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A local extraction process that reads both databases and file feeds, writes timestamped Parquet/file outputs, and creates a manifest with batch ID, mode, watermark, row counts, and checksums. You will design failure and watermark behavior before relying on incremental mode.

2. Why it matters

A batch is the unit of movement, retry, audit, and reconciliation. Without a stable batch ID and manifest, a cloud upload is just a collection of files whose origin and completeness cannot be proved.

3. Words to know

Term	Plain-language definition
Extraction	Reading data out of a source without yet applying business transformation.
Full extraction	Read the complete selected source scope.
Incremental extraction	Read rows new/changed after a stored source position.
High-water mark	Latest source timestamp/position fully committed by a successful batch.
Tie-breaker	Second key used when many rows share a timestamp.
Manifest	Batch inventory with counts, checksums, paths, mode, and status.
Parquet	Columnar file format preserving types efficiently.
Checksum	SHA-256 file fingerprint.
Atomic handoff	Consumer sees a complete batch, not partially written files.
Idempotency	Safe repeat behavior for the same logical extraction window.
Batch status	RUNNING/SUCCESS/FAILED evidence.
Partial failure	Some files written before the process stops.

4. What must already be completed

Both source databases are populated/reconciled; file feeds exist; `.env` works; `.venv` active; enough disk space is available.

5. Applications to open

Application	How to open it	Why it is open
VS Code	Open extractor, manifest examples, and runbook.	Understand logic before execution.
Windows PowerShell	Repository root with <code>.venv</code> active.	Run full/incremental extract and checks.
SSMS and pgAdmin	Source contexts.	Verify watermark/update columns and independent counts.
File Explorer	Open generated batch folder.	Confirm immutable folder shape before upload.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
<code>python -m scripts.extraction.extract_local_sources --mode full --file-feed-dir datasets\sample\files --output-root datasets\raw</code>	Reads local sources and writes one timestamped batch folder.	A full baseline is the safest first handoff.
<code>Get-ChildItem datasets\raw -Directory Sort-Object LastWriteTime -Descending Select-Object -First 1 FullName, Name, LastWriteTime</code>	Finds the newest batch folder without guessing its timestamp.	The exact folder name becomes workflow batch ID.
<code>Get-Content datasets\raw\EXT-YYYYMMDDTH-HMMSSZ\batch_manifest.json</code>	Prints manifest.	You should inspect evidence before upload.
<code>Get-FileHash datasets\raw\EXT-YYYYMMDDTH-HMMSSZ\sqlserver\orders.parquet -Algorithm SHA256</code>	Computes SHA-256 independently.	Proves local bytes match manifest.
<code>SELECT COUNT_BIG(*) AS orders, MAX(updated_at) AS max_updated_at FROM erp.orders;</code>	Gets independent source count and candidate watermark.	Manifest must reconcile to source and watermarks need evidence.
<code>SELECT COUNT(*) AS sessions, MAX(created_at) AS max_created_at FROM digital.web_sessions;</code>	Gets digital count and event/source position evidence.	PostgreSQL tables may not share the same update column strategy.

Incremental decision rule

A generic `WHERE updated_at > watermark` is not valid for every table: some tables have only `created_at`, snapshots use a business date, events may be append-only, and file feeds use filenames/dates/checksums. A production-ready extractor stores a watermark per source object and may use `(updated_at, primary_key)` to avoid equal-timestamp gaps.

Failure rule

Write to a unique batch folder, keep status `FAILED` on exception, do not publish/upload it as trusted, and do not advance the committed watermark. A later run can retry the same logical bounds with a new attempt ID or safely replace the failed folder under an explicit policy.

MY TASK

Run/reconcile a full batch, independently verify one checksum, simulate one safe failure, and refactor/design per-table incremental metadata with a tie-breaker for at least orders and web events.

STARTER SKELETON

```
# config/incremental_sources.example.yml
sources:
- source_system: SQLSERVER_ERP
  table: erp.orders
  watermark_column: updated_at
  tie_breaker_column: order_id
  last_success_value: TODO(USER)
  last_success_tie_breaker: TODO(USER)
- source_system: POSTGRES_DIGITAL
```

```

table: digital.web_events
strategy: append_only
watermark_column: event_timestamp
tie_breaker_column: event_id
last_success_value: TODO(USER)

```

TODO(USER): state when values are committed and how deleted rows are handled.

Acceptance criteria: One full batch has exact source/file reconciliation and checksum proof; failed batch behavior is recorded; incremental design is per table with committed watermark/tie-breaker policy.

HINT 1 — CONCEPT

Watermark is a success checkpoint, not simply MAX(source) at process start.

HINT 2 — PSEUDOCODE

Use the primary key as a tie-breaker when timestamps can repeat.

HINT 3 — NEAR-COMPLETE PATTERN

Adapt the manifest structure already written; add attempt/status/watermark metadata before changing extraction filters.

13. Expected files or output

- datasets/raw/EXT-.../ with sqlserver, postgres, files, manifest.
- Source-to-extract count matrix.
- Independent checksum match.
- FAILED practice manifest/evidence.
- Per-table incremental strategy document or config skeleton.

14. How to verify

- Every manifest file exists and hash matches.
- Full counts equal source counts.
- Failed attempt is not labeled SUCCESS.
- No watermark was advanced from failed attempt.
- Exact batch ID is ready for volume upload.

15. Automated tests

- Manifest schema/required fields test (add as user task).
- Checksum recomputation.
- Source count SQL reconciliation.
- Incremental boundary tests with equal timestamps and no-change rerun.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
updated_at column not found	Generic incremental filter applied to a table without that column.	Inspect data dictionary/ source schema.	Use per-table strategy and column mapping; full mode until implemented.	Each query uses valid source column.
Manifest FAILED	Source/file/permission/write error occurred.	Read error field and terminal exception.	Fix root cause; do not upload partial batch; rerun.	New complete SUCCESS batch reconciles.
Checksum differs	File changed, wrong path, or text transfer altered bytes.	Compare size/time/path; re-compute local and uploaded copy later.	Use immutable binary upload and exact batch folder.	Hashes match.
Parquet package error	pyarrow missing/wrong environment.	python -m pip show pyarrow; interpreter path.	Install requirements in .env.	Small Parquet write/read succeeds.
Disk space failure	Output/portfolio scale too large.	Get-PSDrive -Name C and batch size.	Use quick/small, clear only known failed/generated folders after backup.	Full batch completes.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why is a manifest more than a file list?
2. When should a watermark advance?
3. Why might (timestamp, key) be safer than timestamp alone?
4. What happens to a partial failed batch?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which extraction mode should establish the first baseline?
2. What does a checksum prove and not prove?
3. Why does one generic updated_at filter fail across these sources?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture the SUCCESS manifest, source count queries, and matching checksum. Also capture the safe FAILED attempt status without exposing credentials.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: extract manifest-driven local source batches
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

- ☐ Full batch extracted — [STATUS]
- ☐ All files/counts reconciled — [STATUS]
- ☐ Checksum independently verified — [STATUS]
- ☐ Failure behavior tested — [STATUS]
- ☐ Watermark commit rule explained — [STATUS]
- ☐ Per-table incremental design completed — [STATUS]
- ☐ Batch ready for Databricks upload — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-7. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-7] (the answer-key section immediately after the quiz in this workbook#phase-7).

Next phase: Phase 8 creates and verifies the Databricks workspace resources that will receive this exact batch.

Required action cards

Action 7.2.1 — Open scripts/extraction/extract_local_sources.py. Identify source table lists, batch ID creation, output fol

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open scripts/extraction/extract_local_sources.py. Identify source table lists, batch ID creation, output fol. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open scripts/extraction/extract_local_sources.py. Identify source table lists, batch ID creation, output folder, checksum, and finally manifest write.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Open scripts/extraction/extract_local_sources.py. Identify source table lists, batch ID creation, output folder, checksum, and finally manifest write.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.2.2 — Open docs/runbook.md. Note that watermark advances only after successful downstream acceptance—not merely af

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Open docs/runbook.md. Note that watermark advances only after successful downstream acceptance—not merely af. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open docs/runbook.md. Note that watermark advances only after successful downstream acceptance—not merely after one file writes.
4. Pause while the application finishes the operation; do not click the same control twice.

5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

Open `docs/runbook.md`. Note that watermark advances only after successful downstream acceptance—not merely after one file writes.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.2.3 — For the first batch, use full mode. This establishes a known baseline and avoids pretending incremental logic

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

For the first batch, use full mode. This establishes a known baseline and avoids pretending incremental logic. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: For the first batch, use full mode. This establishes a known baseline and avoids pretending incremental logic is verified.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

For the first batch, use full mode. This establishes a known baseline and avoids pretending incremental logic is verified.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.2.8 — Design incremental behavior: choose updated_at only for tables that have it, a tie-breaker key for equal tim

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Design incremental behavior: choose updated_at only for tables that have it, a tie-breaker key for equal tim. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Design incremental behavior: choose updated_at only for tables that have it, a tie-breaker key for equal timestamps, and a separate strategy for append-only/event tables or snapshots.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 8

Action

Design incremental behavior: choose updated_at only for tables that have it, a tie-breaker key for equal timestamps, and a separate strategy for append-only/event tables or snapshots.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.2.9 — Simulate a failure safely by pointing a practice run to a missing file-feed folder or invalid output—not by co

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Simulate a failure safely by pointing a practice run to a missing file-feed folder or invalid output—not by co. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Simulate a failure safely by pointing a practice run to a missing file-feed folder or invalid output—not by corrupting source data. Inspect FAILED manifest and confirm no watermark is advanced.
4. Pause while the application finishes the operation; do not click the same control twice.

5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 9****Action**

Simulate a failure safely by pointing a practice run to a missing file-feed folder or invalid output—not by corrupting source data. Inspect FAILED manifest and confirm no watermark is advanced.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

Action 7.2.10 — Complete TODO: store per-table watermarks rather than applying one generic updated_at filter to tables that

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Complete TODO: store per-table watermarks rather than applying one generic updated_at filter to tables that . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Complete TODO: store per-table watermarks rather than applying one generic updated_at filter to tables that do not have that column. The workbook reference extractor is intentionally a teaching skeleton here.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 10

Action

Complete TODO: store per-table watermarks rather than applying one generic updated_at filter to tables that do not have that column. The workbook reference extractor is intentionally a teaching skeleton here.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.2.C1 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.extraction.extract_local_sources --mode full --file-feed-dir datasets\sample\files --output-root datasets\raw
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m scripts.extraction.extract_local_sources --mode full --file-feed-dir datasets\sample\files --output-root datasets\raw` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.extraction.extract_local_sources` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--mode` is a command option or flag; its exact behavior is defined beside the command; `full` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--file` is a command option or flag; its exact behavior is defined beside the command; `-feed` is a command option or flag; its exact behavior is defined beside the command; `-dir` is a command option or flag; its exact behavior is defined beside the command; `datasets` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `sample` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `files` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--output` is a command option or flag; its exact behavior is defined beside the command; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.2.C2 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-ChildItem datasets\raw -Directory | Sort-Object LastWriteTime -Descending | Select-Object -First 1 FullName, Name, LastWriteTime
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Get-ChildItem datasets\raw -Directory | Sort-Object LastWriteTime -Descending | Select-Object -First 1 FullName, Name, LastWriteTime — Get-ChildItem lists files and folders; datasets is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; raw is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Directory is a command option or flag; its exact behavior is defined beside the command; Sort-Object is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; LastWriteTime is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Descending is a command option or flag; its exact behavior is defined beside the com-

mand; `Select-Object` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-First` is a command option or flag; its exact behavior is defined beside the command; `1` is a numeric literal used by the command or expression; `FullName` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

[Back to the Phase 7 lesson index](#)

Action 7.2.C5 — SSMS query window

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT COUNT_BIG(*) AS orders, MAX(updated_at) AS max_updated_at FROM erp.orders;
```

Where to enter it:

SSMS query window. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT COUNT_BIG(*) AS orders, MAX(updated_at) AS max_updated_at FROM erp.orders;` — `SELECT` requests data without changing it unless combined with a modifying statement; `COUNT_BIG` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(*)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `orders` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `MAX` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `max_updated_at` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.2.C6 — pgAdmin Query Tool

Application:

pgAdmin 4 or PostgreSQL psql, as named in the action

Window or panel:

pgAdmin Query Tool

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT COUNT(*) AS sessions, MAX(created_at) AS max_created_at FROM digital.web_sessions;
```

Where to enter it:

pgAdmin Query Tool. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT COUNT(*) AS sessions, MAX(created_at) AS max_created_at FROM digital.web_sessions; — SELECT requests data without changing it unless combined with a modifying statement; COUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (*) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; sessions is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; MAX is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; created_at is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; AS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; max_created_at is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; remaining punctuation and identifiers continue the same statement.

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 7.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 7 starting-screen checklist and re-verify the active context.

Lesson 7.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 7 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — scripts/

Exact folder name: `scripts`

Exact parent: `repository root`

Why it is needed now: Phase 7 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `scripts`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 7.D1.1 — Create the folder scripts

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\scripts" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run Test-Path ".\scripts" -PathType Container.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — scripts/extraction/

Exact folder name: extraction

Exact parent: scripts

Why it is needed now: Phase 7 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path scripts one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: extraction.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 7.D2.1 — Create the folder scripts/extraction

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\scripts\utilities" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — `scripts/extraction/extract_local_sources.py`

Exact filename: `extract_local_sources.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/extraction` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 7.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in scripts/extraction one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `extract_local_sources.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `extract_local_sources.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 7.F1.1 — Create the file `scripts/extraction/extract_local_sources.py` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\extraction\extract_local_sources.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\scripts\extraction\extract_local_sources.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts\extraction\extract_local_sources.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\scripts\extraction\extract_local_sources.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/extraction/extract_local_sources.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/extraction`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/extraction/extract_local_sources.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\extraction\extract_local_sources.py"` and require `True`.
4. Run `git status --short -- "scripts/extraction/extract_local_sources.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `scripts/extraction/extract_local_sources.py`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/extraction/extract_local_sources.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 7.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

[Back to the Phase 7 lesson index](#)

File introduction — `scripts/utilities/checksums.py`

Exact filename: `checksums.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/utilities` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 7.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `scripts/utilities` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `checksums.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `checksums.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 7.F2.1 — Create the file `scripts/utilities/checksums.py` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\utilities\checksums.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\scripts\utilities\checksums.py" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts\utilities\checksums.py" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\scripts\utilities\checksums.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/utilities/checksums.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/utilities`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/utilities/checksums.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\utilities\checksums.py"` and require `True`.
4. Run `git status --short -- "scripts/utilities/checksums.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for scripts/utilities/checksums.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/utilities/checksums.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 7.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
"""Small checksum functions used by extraction and reconciliation scripts."""
from __future__ import annotations

import hashlib
from pathlib import Path

def sha256_file(path: str | Path) -> str:
    """Return the SHA-256 checksum of a file without loading it all into memory."""
    file_path = Path(path)
    digest = hashlib.sha256()
    with file_path.open("rb") as handle:
        for chunk in iter(lambda: handle.read(1024 * 1024), b""):
            digest.update(chunk)
    return digest.hexdigest()
```

File introduction — `scripts/utilities/database.py`

Exact filename: `database.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/utilities` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 7.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.

2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in scripts/utilities one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `database.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `database.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 7.F3.1 — Create the file `scripts/utilities/database.py` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\utilities\database.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\scripts\utilities\database.py" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is

a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts\utilities\database.py" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\scripts\utilities\database.py" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add -Force, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/utilities/database.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under scripts/utilities.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with scripts/utilities/database.py.
3. In PowerShell at the repository root, run Test-Path ".\scripts\utilities\database.py" and require True.
4. Run git status --short -- "scripts/utilities/database.py" to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for scripts/utilities/database.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: scripts/utilities/database.py

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 7.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

[Back to the Phase 7 lesson index](#)

What your screen should look like now

- Every Phase 7 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 7.3 completion checklist

☐

scripts/extraction/extract_local_sources.py was created by me, saved, located correctly, and inspected — [STATUS]

☐

scripts/utilities/checksums.py was created by me, saved, located correctly, and inspected — [STATUS]

☐

scripts/utilities/database.py was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 7.4](#) and recheck the root and branch.

Lesson 7.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Action 7.4.G1 — Inspect the current state without changing it

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Inspect the current state without changing it. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Record the exact starting folders, branch, versions, connections, settings, counts, or evidence.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.4.G2 — Create the smallest required object or decision

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Create the smallest required object or decision. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use the phase file tutorial and one bounded action card.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.4.G3 — Run the phase-specific verification

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run the phase-specific verification. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Compare actual output with the required condition and record differences.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Action 7.4.G4 — Demonstrate one safe failure or alternate-result branch

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Demonstrate one safe failure or alternate-result branch. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Use a toy/disposable case and prove recovery without damaging verified work.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

Action 7.4.G5 — Record evidence and prepare the downstream handoff

Application:

VS Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Record evidence and prepare the downstream handoff. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

VS Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. Save the verified input that the next phase consumes.
2. Inspect the result.
3. Record the actual value.
4. Continue only after verification.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 7 lesson index](#)

What your screen should look like now

- The new Phase 7 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 7.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 7.5](#).

Lesson 7.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 7 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — CSV versus Parquet extracts

Question:

Which local interchange format should the beginner path use?

Options considered:

- CSV/JSON plus manifest.
- Parquet.
- Direct JDBC from Databricks to localhost.

Beginner path selected:

Use CSV and JSON with manifests and checksums for Track A.

Why this path was selected:

The files are inspectable with basic tools and make schema/quoting issues visible.

Tradeoff:

They are larger and less type-safe than Parquet.

What a company might do instead:

Production pipelines often use Parquet/Delta in cloud object storage and CDC or direct networked ingestion.

How to explain this in an interview:

I chose inspectable files for the local handoff, added checksums and manifests, and documented Parquet as a scale-oriented alternative.

Design decision — Full versus incremental loading

Question:

When should the extractor read every source row and when should it read only new or changed rows?

Options considered:

- Full extraction for every run.
- Incremental extraction from the first run.
- A full baseline followed by audited incremental batches.

Beginner path selected:

Create and reconcile one full baseline, then use incremental extraction with a timestamp-plus-key boundary and advance the watermark only after success.

Why this path was selected:

The baseline proves completeness and supplies a recovery point; incremental batches then teach efficiency, replay safety, and late/change handling.

Tradeoff:

Two modes require more tests, metadata, and correction logic than a full-only learning pipeline.

What a company might do instead:

A company may use CDC, transaction-log positions, event streams, snapshot isolation, backfill tooling, and automated restart/reconciliation controls.

How to explain this in an interview:

I established a full baseline before introducing incremental watermarks so efficiency did not replace completeness or recoverability.

If you see Result A

The full baseline reconciles and the incremental batch advances its watermark only after success. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

No rows qualify, duplicate timestamps create an ambiguous boundary, or a failed batch has partial output. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: VS Code, PowerShell, SSMS, pgAdmin, Python, and File Explorer.

Window/panel: Show successful manifest, checksum, watermark, source counts, and a safe failed-attempt record.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase07_build-full-and-incremental-local-extraction_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 7's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 7 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 7.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.

7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Interpret `git status --short`

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 7.5.G4 — Inspect the unstaged diff for scripts/extraction/extract_local_sources.py

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "scripts/extraction/extract_local_sources.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "scripts/extraction/extract_local_sources.py"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding ex-

planation; -- is a command option or flag; its exact behavior is defined beside the command; "scripts/extraction/extract_local_sources.py" is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.5.G5 — Stage only the reviewed file scripts/extraction/extract_local_sources.py

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "scripts/extraction/extract_local_sources.py"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "scripts/extraction/extract_local_sources.py"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"scripts/extraction/extract_local_sources.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 7.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches `The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.5.G7 — Create the Phase 7 commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: add manifest-driven incremental extracts"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: add manifest-driven incremental extracts"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: add manifest-driven incremental extracts"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

`git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Action 7.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 7 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message feat: add manifest-driven incremental extracts and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 7.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 7 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 7 created the verified boundary described by **Build full and incremental local extraction**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 7 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 7.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 8 creates the cloud landing location that receives those local batches.

Phase 7 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 8 — Configure Databricks, governed storage, notebooks, and compute

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: A valid local batch, manifest, and verified Databricks environment.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 9 ingests that exact batch into append-only raw Delta tables.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 8 lesson index

1. [Lesson 8.1 — Understand the phase and starting screen](#)
2. [Lesson 8.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 8.3 — Create and understand the phase files](#)
4. [Lesson 8.4 — Build and validate required objects](#)
5. [Lesson 8.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 8.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Web browser, Databricks workspace, VS Code, and File Explorer.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 8 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 7 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 8 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Web browser, Databricks workspace, VS Code, and File Explorer. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 8 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 8 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 8 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 8.1 completion checklist

☐

I read why Phase 8 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 8.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 8 lesson index](#)

Lesson 8.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 8 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

An available Databricks workspace configured with a usable catalog, landing, bronze, silver, gold, and quality schemas, a governed volume for Track A files, Git-friendly source notebooks, and a successful `00_environment_check` run using the exact uploaded batch ID.

2. Why it matters

Databricks is the remote lakehouse and orchestration environment. Before transforming data, you must prove identity, object permissions, storage paths, Spark, parameters, and Delta read/write. This isolates environment failures from business-code failures.

3. Words to know

Term	Plain-language definition
Workspace	Databricks environment containing notebooks, data, compute, SQL, and Jobs.
Compute	Resources that execute Spark/SQL. Free Edition commonly provides serverless managed compute subject to quotas.
Catalog	Top governed namespace in Unity Catalog.
Schema	Namespace below a catalog for tables/volumes.
Volume	Governed file storage for non-tabular files and batch handoff.
Notebook	Document with executable cells and Markdown.
Git folder	Databricks workspace folder linked to a Git repository; older documentation may call it Repos.
Cluster	User-configured Spark compute; availability varies by tier.
SQL warehouse	Compute endpoint for Databricks SQL and BI queries.
Secret	Protected credential value referenced without printing it.
Widget	Notebook input parameter.
Task value	Small output passed/recorded between Job tasks.
Serverless	Provider-managed compute; feature/quotas vary by workspace.
Catalog Explorer	UI for catalogs, schemas, tables, volumes, and permissions.

4. What must already be completed

A verified SUCCESS extraction batch exists. Databricks account/workspace availability and current limitations were reviewed in Phase 2. The feature branch is pushed if using Git folder integration.

5. Applications to open

Application	How to open it	Why it is open
Web browser	Open the Databricks workspace URL.	Create/inspect workspace objects and run notebook.
VS Code	Open databricks/notebooks/00_environment_check.py and databricks/README.md.	Understand every cell before importing/running.
File Explorer	Open exact local datasets/raw/EXT-... batch.	Upload the correct immutable folder.
Windows PowerShell	Repository root.	Read manifest and verify batch ID/checksums before upload.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
<code>\$BatchId = 'EXT-YYYYMMDDTHHMMSSZ'; Get-Content "data-sets\raw\$BatchId\batch_manifest.json"</code>	Prints the local manifest before upload.	The remote parameter must match a complete local batch.
<code>print(spark.version)</code>	Prints Spark and resolved parameters/path.	Hidden defaults cause wrong-catalog and wrong-batch failures.
<code>SHOW SCHEMAS IN northstar_retail;</code>	Lists schemas in the chosen catalog.	Verifies namespaces independently of notebook variables.
<code>dbutils.fs.ls(f"/Volumes/{catalog}/{landing_schema}/{volume}/{batch_id}")</code>	Lists uploaded batch contents.	Proves compute can access the exact handoff.
<code>SELECT * FROM northstar_retail.quality.environment_check ORDER BY checked_at_utc DESC LIMIT 10;</code>	Reads the Delta test table written by Spark.	Proves table creation and SQL access.

Compute choice summary

- Use available serverless notebook/job compute for Track A when the workspace provides it.
- A SQL warehouse runs Databricks SQL and BI queries; it is not the same execution surface as a PySpark notebook task.
- Free Edition is quota-limited and, as verified on 2026-08-16, Jobs concurrency is limited; the documented graph stays below five parallel tasks. Verify current limits again when you run.

Catalog fallback

If `CREATE CATALOG` is denied, do not request administrator rights merely for a name. Use a writable catalog, record it, and pass it consistently. The architecture is about governed namespaces, not the literal string `northstar_retail`.

MY TASK

Create/identify the governed namespaces and volume, upload one exact SUCCESS batch, import/sync the notebooks, run `00_environment_check`, and document any tier/UI variance with a screenshot and official source.

STARTER SKELETON

```
TODO(USER) Databricks environment record
Workspace/tier/cloud: _____
Catalog actually used: _____
Schemas: _____
Volume path: _____
Git folder path or import fallback: _____
Compute type: _____
SQL warehouse availability: _____
Batch ID: _____
Environment check run ID/time: _____
Tier/UI variance and official source: _____
```

Acceptance criteria: The exact batch path is readable, the test Delta table contains a PASS row, all parameters are recorded, and no notebook contains a token/password.

HINT 1 — CONCEPT

Use actual writable resources; names are parameters, not hard-coded truth.

HINT 2 — PSEUDOCODE

Resolve volume path from catalog/schema/volume and append the exact manifest batch_id.

HINT 3 — NEAR-COMPLETE PATTERN

Run the environment notebook reference in this workbook cell by cell, comparing output to the environment record.

13. Expected files or output

- Five schemas in a writable catalog.
- Managed volume with preserved batch folder.
- Workspace Git folder or documented import fallback.
- PASS row in quality.environment_check.
- Spark/version/path parameter evidence.
- No Track B credential requirement for Track A.

14. How to verify

- Volume browser and `dbutils.fs.ls` show the same files.
- Batch ID matches local manifest.
- Spark can write/read Delta table.
- Catalog Explorer can preview the table.
- Git folder points to intended repository/branch or fallback is documented.

15. Automated tests

- `00_environment_check` assertions.
- Manual uploaded checksum comparison for at least one file if tooling permits download/read.
- Environment status task value equals PASS when run as a Job later.
- No secret scanner finding in Git.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
PERMISSION_DENIED creating catalog/schema/volume	Workspace identity lacks privilege.	Inspect object named in error; <code>SHOW CATALOGS/grants</code> if allowed.	Use permitted catalog/schema or request minimum grant; do not use admin token workaround.	Environment check writes table.
Batch path not found	Upload flattened/renamed/wrong parameter.	Volume browser; print batch_root; compare manifest ID.	Recreate exact folder structure and parameter.	ls returns contents.

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
Git folder authentication fails	Credential/provider/branch configuration issue.	Workspace user settings and official Git folder docs.	Use supported OAuth/PAT securely or manual import fallback.	Notebooks visible and current.
Compute unavailable/quota exceeded	Tier quota or temporary capacity.	Workspace banner/run error and limits page.	Use quick data, stop repeated retries, resume when quota permits; do not claim run.	Environment run completes.
Notebook creates wrong catalog	Default widgets not replaced.	Print widgets/current_catalog.	Set job/notebook parameters consistently; clean accidental disposable object only after review.	Objects live in recorded catalog.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why does Track A use a volume instead of JDBC to localhost?
2. What is the difference between Spark compute and a SQL warehouse?
3. Why is environment validation a separate first task?
4. What should you do when the UI differs from the workbook?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What path pattern identifies a Unity Catalog volume?
2. Which parameter must exactly match the extraction folder?
3. Why are Databricks secrets unnecessary for local-source ingestion in Track A?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture Catalog Explorer with schemas/volume, the preserved batch folder, and the environment-check PASS output/table. Hide personal email where unnecessary.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
docs: verify databricks workspace and track a volume handoff
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Workspace/tier documented — [STATUS]

☐

Writable catalog chosen — [STATUS]

☐

Schemas created — [STATUS]

☐

Volume and batch uploaded — [STATUS]

☐

Git/import path established — [STATUS]

☐

Environment notebook passed — [STATUS]

☐

Delta table verified — [STATUS]

☐

No secret exposed — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-8. The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-8] (the answer-key section immediately after the quiz in this workbook#phase-8).

Next phase: Phase 9 ingests the uploaded SQL Server, PostgreSQL, CSV, and JSON extracts into Bronze Delta tables.

Required action cards

Action 8.2.1 — Sign in to the available Databricks workspace. Record cloud/region/workspace tier and today's date. Free Editi

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Sign in to the available Databricks workspace. Record cloud/region/workspace tier and today's date. Free Editi. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Sign in to the available Databricks workspace. Record cloud/region/workspace tier and today's date. Free Edition and paid workspaces can show different menus and privileges.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 1

Action

Sign in to the available Databricks workspace. Record cloud/region/workspace tier and today's date. Free Edition and paid workspaces can show different menus and privileges.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Action 8.2.2 — In the left navigation, open or . Look for an existing writable catalog. If you can create one, choose and nam

Application:

Databricks workspace in a web browser

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

In the left navigation, open or . Look for an existing writable catalog. If you can create one, choose and nam. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: In the left navigation, open **Catalog** or **Catalog Explorer**. Look for an existing writable catalog. If you can create one, choose **Create catalog** and name it `northstar_retail`. If permission is denied, use a catalog the workspace grants, commonly `workspace`, and pass that actual name to every widget/job parameter.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Databricks workspace in a web browser. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 2****Action**

In the left navigation, open **Catalog** or **Catalog Explorer**. Look for an existing writable catalog. If you can create one, choose **Create catalog** and name it `northstar_retail`. If permission is denied, use a catalog the workspace grants, commonly `workspace`, and pass that actual name to every widget/job parameter.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Action 8.2.3 — Inside the chosen catalog, create schemas landing, bronze, silver, gold, and quality using or the SQ

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Inside the chosen catalog, create schemas landing, bronze, silver, gold, and quality using or the SQ. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Inside the chosen catalog, create schemas landing, bronze, silver, gold, and quality using **Create > Schema** or the SQL editor. Add descriptive comments when the UI allows.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

Inside the chosen catalog, create schemas landing, bronze, silver, gold, and quality using **Create > Schema** or the SQL editor. Add descriptive comments when the UI allows.

Before continuing

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Action 8.2.4 — Open landing; choose , name it track_a_files, and choose a managed volume unless your workspace administra

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The selected Databricks workspace, catalog, schema, volume, notebook, or Job named in the action.

What you are about to do:

Open landing; choose , name it track_a_files, and choose a managed volume unless your workspace administra. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open landing; choose **Create > Volume**, name it `track_a_files`, and choose a managed volume unless your workspace administrator has defined an external location. Record the volume path / Volumes/<catalog>/landing/track_a_files.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 4****Action**

Open landing; choose **Create > Volume**, name it `track_a_files`, and choose a managed volume unless your workspace administrator has defined an external location. Record the volume path /Volumes/<catalog>/landing/track_a_files.

Before continuing☐

I used the application named in this phase.
