File introduction — sql/sqlserver/warehouse/02_create_staging_tables.sql

Exact filename: 02_create_staging_tables.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/sqlserver/warehouse relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 15.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/sqlserver/warehouse one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 02_create_staging_tables.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 02_create_staging_tables.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 15.F2.1 — Create the file sql/sqlserver/warehouse/02_create_staging_tables.sql from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.

3. **CLICK:** Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. **TYPE THIS:** Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. **PRESS:** Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. **LOOK FOR:** Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. **DO NOT CONTINUE UNTIL:** Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\warehouse\02_create_staging_tables.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\warehouse\02_create_staging_tables.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.\sql\sqlserver\warehouse\02_create_staging_tables.sql` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches

If the command creates the file

Run `Test-Path -LiteralPath ".\sql\sqlserver\warehouse\02_create_staging_tables.sql" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/warehouse/02_create_staging_tables.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODD(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/warehouse`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/warehouse/02_create_staging_tables.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\warehouse\02_create_staging_tables.sql"` and require True.
4. Run `git status --short -- "sql/sqlserver/warehouse/02_create_staging_tables.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/warehouse/02_create_staging_tables.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/warehouse/02_create_staging_tables.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 15.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: SQL Server / T-SQL
-- Purpose: create empty staging tables that mirror warehouse targets.
-- Run after 01_create_warehouse.sql in NorthstarRetail_DW.
USE NorthstarRetail_DW;
GO

DECLARE @table sysname;
DECLARE table_cursor CURSOR LOCAL FAST_FORWARD FOR
SELECT name FROM sys.tables WHERE schema_id = SCHEMA_ID('dw');
OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table;
WHILE @@FETCH_STATUS = 0
BEGIN
```

```

DECLARE @stage sysname = N'stg_' + @table;
IF OBJECT_ID(QUOTENAME('stg') + N'.' + QUOTENAME(@stage), N'U') IS NULL
BEGIN
    DECLARE @sql nvarchar(max) = N'SELECT TOP (0) * INTO stg.' + QUOTENAME(@stage) + N' FROM dw.' + QUOTENAME(@table) + N';';
    EXEC sys.sp_executesql @sql;
END;
FETCH NEXT FROM table_cursor INTO @table;
END;
CLOSE table_cursor;
DEALLOCATE table_cursor;
GO
SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='stg' ORDER BY TABLE_NAME;

```

Line-by-line explanation

- **Line 1:** -- Dialect: SQL Server / T-SQL is a comment for a human reader; it normally does not change data or execute business logic.

File introduction — `scripts/loading/load_gold_to_sqlserver.py`

Exact filename: `load_gold_to_sqlserver.py`

Filename extension: `.py`. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `scripts/loading` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: executable Python logic for Phase 15.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `scripts/loading` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `load_gold_to_sqlserver.py`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `load_gold_to_sqlserver.py` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 15.F3.1 — Create the file scripts/loading/load_gold_to_sqlserver.py from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\loading\load_gold_to_sqlserver.py" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\scripts\loading\load_gold_to_sqlserver.py" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts\loading\load_gold_to_sqlserver.py" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\scripts\loading\load_gold_to_sqlserver.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/loading/load_gold_to_sqlserver.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `scripts/loading`.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with `scripts/loading/load_gold_to_sqlserver.py`.
3. In PowerShell at the repository root, run `Test-Path ".\scripts\loading\load_gold_to_sqlserver.py"` and require `True`.
4. Run `git status --short -- "scripts/loading/load_gold_to_sqlserver.py"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `scripts/loading/load_gold_to_sqlserver.py`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Python

Exact file: `scripts/loading/load_gold_to_sqlserver.py`

Purpose: executable Python logic.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 15.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
"""Track A local loader: publish downloaded Gold exports to NorthstarRetail_DW safely.

The required beginner mode is ``full-dev`` for a disposable learning warehouse. It stages and
validates every table before changing targets, deletes child facts before parent dimensions,
inserts parents before children with explicit noncomputed columns, and commits once.

File introduction — sql/sqlserver/validation/02_validate_warehouse.sql

Exact filename: 02_validate_warehouse.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/sqlserver/validation relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 15.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/sqlserver/validation one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 02_validate_warehouse.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 02_validate_warehouse.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 15.F4.1 — Create the file `sql/sqlserver/validation/02_validate_warehouse.sql` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\validation\02_validate_warehouse.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\validation\02_validate_warehouse.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\validation\02_validate_warehouse.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\sqlserver\validation\02_validate_warehouse.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/validation/02_validate_warehouse.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/validation`.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/validation/02_validate_warehouse.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\validation\02_validate_warehouse.sql"` and require `True`.
4. Run `git status --short -- "sql/sqlserver/validation/02_validate_warehouse.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/validation/02_validate_warehouse.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/validation/02_validate_warehouse.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 15.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: SQL Server / T-SQL
USE NorthstarRetail_DW;
GO

-- Duplicate fact grain should be zero.

[Back to the Phase 15 lesson index](#)

File introduction — sql/sqlserver/warehouse/03_semantic_views.sql

Exact filename: 03_semantic_views.sql

Filename extension: .sql. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: sql/sqlserver/warehouse relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: database or lakehouse definitions and queries for Phase 15.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in sql/sqlserver/warehouse one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: 03_semantic_views.sql.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled 03_semantic_views.sql and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 15.F5.1 — Create the file sql/sqlserver/warehouse/03_semantic_views.sql from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\warehouse\03_semantic_views.sql" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\sql\sqlserver\warehouse\03_semantic_views.sql" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\sql\sqlserver\warehouse\03_semantic_views.sql" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\sqlserver\warehouse\03_semantic_views.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/warehouse/03_semantic_views.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `sql/sqlserver/warehouse`.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with `sql/sqlserver/warehouse/03_semantic_views.sql`.
3. In PowerShell at the repository root, run `Test-Path ".\sql\sqlserver\warehouse\03_semantic_views.sql"` and require True.
4. Run `git status --short -- "sql/sqlserver/warehouse/03_semantic_views.sql"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `sql/sqlserver/warehouse/03_semantic_views.sql`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: SQL

Exact file: `sql/sqlserver/warehouse/03_semantic_views.sql`

Purpose: database or lakehouse definitions and queries.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 15.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
-- Dialect: SQL Server / T-SQL

What your screen should look like now

- Every Phase 15 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 15.3 completion checklist

☐

sql/sqlserver/warehouse/01_create_warehouse.sql was created by me, saved, located correctly, and inspected — [STATUS]

☐

sql/sqlserver/warehouse/02_create_staging_tables.sql was created by me, saved, located correctly, and inspected — [STATUS]

☐

scripts/loading/load_gold_to_sqlserver.py was created by me, saved, located correctly, and inspected — [STATUS]

☐

sql/sqlserver/validation/02_validate_warehouse.sql was created by me, saved, located correctly, and inspected — [STATUS]

☐

sql/sqlserver/warehouse/03_semantic_views.sql was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 15.4](#) and recheck the root and branch.

Lesson 15.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

SQL Server warehouse object 1 — `dw.dim_date`

Object type: dimension.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: `load_batch_id`, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W1 — Create, load, and validate `dw.dim_date`

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.dim_date. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_date.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_date.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 15 lesson index](#)

Teaching DDL skeleton

```
IF OBJECT_ID(N'dw.dim_date', N'U') IS NULL
BEGIN
    CREATE TABLE dw.dim_date
    (
        -- TODO(USER): add the mapped columns and SQL Server data types.
        load_batch_id VARCHAR(100) NOT NULL,
        loaded_at DATETIME2(3) NOT NULL DEFAULT SYSUTCDATETIME()
    );
END;
GO
```

Line-by-line explanation

- **Line 1:** IF OBJECT_ID(N'dw.dim_date', N'U') IS NULL — IF begins a conditional decision; OBJECT_ID is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; N is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 'dw.dim_date' is a quoted literal; the quotation marks preserve spaces or mark text; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; N is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 'U' is a quoted literal; the quotation marks preserve spaces or mark text;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; IS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** BEGIN — BEGIN is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** CREATE TABLE dw.dim_date — CREATE defines a new database object; TABLE the database object that stores rows and columns; dw.dim_date is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** (— (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** -- TODO(USER): add the mapped columns and SQL Server data types. is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 6:** load_batch_id VARCHAR(100) NOT NULL, — load_batch_id is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; VARCHAR is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 100 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

tifier, or literal whose project-specific role is described in the surrounding explanation; , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 7:** loaded_at DATETIME2(3) NOT NULL DEFAULT SYSUTCDATETIME() — loaded_at is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; DATETIME2 is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 3 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; NOT reverses a Boolean condition; NULL is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; DEFAULT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; SYSUTCDATETIME is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:**); —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 9:** END; — END is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 10:** GO — GO is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.dim_date through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 2 — dw.dim_customer

Object type: dimension.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W2 — Create, load, and validate dw.dim_customer

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.dim_customer. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_customer.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_customer.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.dim_customer through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 3 — dw.dim_product

Object type: dimension.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W3 — Create, load, and validate dw.dim_product

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.dim_product. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_product.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_product.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.dim_employee through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 6 — dw.dim_supplier

Object type: dimension.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W6 — Create, load, and validate dw.dim_supplier

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.dim_supplier. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_supplier.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_supplier.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.dim_channel through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 9 — dw.dim_campaign

Object type: dimension.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W9 — Create, load, and validate dw.dim_campaign

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.dim_campaign. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_campaign.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.dim_campaign.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.fact_returns through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 12 — dw.fact_inventory_snapshot

Object type: fact.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W12 — Create, load, and validate dw.fact_inventory_snapshot

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.fact_inventory_snapshot. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.fact_inventory_snapshot.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.fact_inventory_snapshot.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.fact_web_sessions.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.fact_web_sessions through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 15 — dw.fact_marketing_spend

Object type: fact.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W15 — Create, load, and validate dw.fact_marketing_spend

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.fact_marketing_spend. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.fact_marketing_spend.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.fact_marketing_spend.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.quality_result. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.quality_result.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.quality_result.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published dw.quality_result through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 18 — dw.reconciliation_result

Object type: audit.

Responsibility: Preserve or present warehouse metadata and loaded tables in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W18 — Create, load, and validate dw.reconciliation_result

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate dw.reconciliation_result. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.reconciliation_result.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns dw.reconciliation_result.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

SQL Server warehouse object 20 — stg.dim_customer

Object type: staging.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W20 — Create, load, and validate stg.dim_customer

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate stg.dim_customer. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns stg.dim_customer.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns stg.dim_customer.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published stg.dim_customer through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 21 — stg.dim_product

Object type: staging.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W21 — Create, load, and validate stg.dim_product

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate stg.dim_product. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published stg.dim_store through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 23 — stg.dim_employee

Object type: staging.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W23 — Create, load, and validate stg.dim_employee

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate `stg.dim_employee`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database `NorthstarRetail_DW` in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns `stg.dim_employee`.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database `NorthstarRetail_DW` in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns `stg.dim_employee`.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published stg.dim_promotion through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 26 — stg.dim_channel

Object type: staging.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W26 — Create, load, and validate stg.dim_channel

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate `stg.dim_channel`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database `NorthstarRetail_DW` in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns `stg.dim_channel`.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database `NorthstarRetail_DW` in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns `stg.dim_channel`.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published stg.fact_sales through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 29 — stg.fact_returns

Object type: staging.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W29 — Create, load, and validate stg.fact_returns

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate stg.fact_returns. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns stg.fact_returns.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns stg.fact_returns.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published stg.fact_shipments through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 32 — stg.fact_web_sessions

Object type: staging.

Responsibility: Preserve or present exported Gold file for the verified batch in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W32 — Create, load, and validate stg.fact_web_sessions

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate `stg.fact_web_sessions`. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns `stg.fact_web_sessions`.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns `stg.fact_web_sessions`.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns reporting.vw_sales.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

- **Line 10:** GO — GO is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published reporting.vw_sales through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 35 — reporting.vw_returns

Object type: semantic view.

Responsibility: Preserve or present warehouse metadata and loaded tables in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W35 — Create, load, and validate reporting.vw_returns

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate reporting.vw_returns. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns reporting.vw_returns.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns reporting.vw_returns.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns reporting.vw_shipments.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Validation matrix

Validation	Exported Gold	SQL Server warehouse	Pass condition	My result
Row count	[ENTER]	[ENTER]	exact match	[ENTER]
Distinct grain key	[ENTER]	[ENTER]	exact match	[ENTER]
Primary amount/quantity	[ENTER]	[ENTER]	documented tolerance	[ENTER]
Unknown key count	[ENTER]	[ENTER]	exact match	[ENTER]
Duplicate load of same batch	n/a	[ENTER]	prevented or idempotent	[ENTER]

Common error and recovery

If a bulk/load operation truncates text, changes decimals, parses dates incorrectly, or fails on constraints, stop the transaction. Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published reporting.vw_shipments through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

SQL Server warehouse object 38 — reporting.vw_marketing

Object type: semantic view.

Responsibility: Preserve or present warehouse metadata and loaded tables in the local dimensional warehouse without inventing direct cloud-to-laptop connectivity.

Grain: Match the corresponding Gold object exactly for dimensions/facts; staging retains one row per exported record; audit tables retain one row per load/check event.

Keys and constraints: Dimensions use surrogate primary keys and business-key/history rules; facts use foreign keys/indexes appropriate to the declared grain; staging favors load/reconciliation metadata before final constraints.

Load metadata: load_batch_id, source filename/checksum, loaded timestamp, row count, and load status.

Rerun rule: The loader identifies the batch and target state before inserting, replacing, or rejecting a duplicate load.

Action 15.4.W38 — Create, load, and validate reporting.vw_marketing

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Create, load, and validate reporting.vw_marketing. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns reporting.vw_marketing.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open SSMS and connect to the verified local SQL Server instance.
2. LOOK FOR: Select database NorthstarRetail_DW in the query-window database list.
3. CLICK: Open the warehouse DDL file that owns reporting.vw_marketing.
4. TYPE THIS: Build the object from the mapped Gold columns, keys, constraints, audit metadata, and declared grain.
5. PRESS: Save the SQL file.
6. PRESS: Execute the object section or the verified ordered script.
7. CLICK: Refresh the target schema in Object Explorer.
8. LOOK FOR: Inspect Columns, Keys, Constraints, and Indexes.
9. CLICK: In File Explorer, locate the current batch's downloaded/exported Gold file; do not use an older batch with the same table name.
10. PRESS: Run the local loader for the staging table or object after checksum/count verification.
11. PRESS: Run row-count, duplicate-key, foreign-key, unknown-member, and amount reconciliation queries.
12. DO NOT CONTINUE UNTIL: The warehouse result matches the exported Gold result within documented tolerance.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

Compare exported schema/values with staging types, preserve the failed batch, correct the mapping, and rerun the staging load. Do not disable constraints globally or edit the exported evidence file.

Interview-ready explanation

"I published reporting.vw_marketing through an honest Track A file handoff, loaded staging with batch metadata, applied dimensional constraints, and reconciled row counts and measures back to the verified Gold export."

What your screen should look like now

- The new Phase 15 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 15.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 15.5](#).

Lesson 15.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 15 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Local export-and-load versus direct JDBC publication

Question:

How should cloud Gold data reach laptop SQL Server?

Options considered:

- Manual verified export and local load.
- Direct Databricks JDBC to localhost.
- Cloud warehouse target.

Beginner path selected:

Use manual export-and-load for Track A.

Why this path was selected:

A cloud workspace cannot normally reach a laptop loopback address; the selected method is honest and reproducible.

Tradeoff:

The handoff is not fully automated.

What a company might do instead:

A company uses routable private connectivity or publishes to a managed cloud warehouse.

How to explain this in an interview:

I avoided false localhost connectivity and used a controlled export with row-count and checksum reconciliation before local warehouse loading.

If you see Result A

Export manifest, staging counts, warehouse counts, and control totals reconcile. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

A file/table is missing, the local loader partially fails, or totals differ across the handoff. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Databricks, File Explorer, PowerShell, SSMS, and Python.

Window/panel: Show export manifest, staging load, warehouse tables, and reconciliation query.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase15_publish-gold-data-into-the-sql-server-dimensional-wareh_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 15's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 15 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. **PRESS:** In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 15.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. **CLICK:** Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. **LOOK FOR:** Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. **CLICK:** Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. **TYPE THIS:** Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. **PRESS:** Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. **LOOK FOR:** Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. **DO NOT CONTINUE UNTIL:** Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Interpret `git status --short`

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.
- `MM` means a staged version exists and the file has additional unstaged edits.
- `A` means staged as a new file.
- `D` means deletion; stop and investigate unless deletion is deliberate.
- `R` means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 15.5.G4 — Inspect the unstaged diff for sql/sqlserver/warehouse/01_create_warehouse.sql

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "sql/sqlserver/warehouse/01_create_warehouse.sql"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "sql/sqlserver/warehouse/01_create_warehouse.sql"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"sql/sqlserver/warehouse/01_create_warehouse.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.5.G5 — Stage only the reviewed file `sql/sqlserver/warehouse/01_create_warehouse.sql`

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "sql/sqlserver/warehouse/01_create_warehouse.sql"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "sql/sqlserver/warehouse/01_create_warehouse.sql"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"sql/sqlserver/warehouse/01_create_warehouse.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 15.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.5.G7 — Create the Phase 15 commit

Application:

SQL Server Management Studio (SSMS)

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.

2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: publish gold into sql server warehouse"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: publish gold into sql server warehouse"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: publish gold into sql server warehouse"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Action 15.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

Usually the repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` plus the database named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches Usually the repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project plus the database named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 15 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message feat: publish gold into sql server warehouse and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 15.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 15 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 15 created the verified boundary described by **Publish Gold data into the SQL Server dimensional warehouse**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

Mini quiz

1. Multiple choice: Why does Phase 15 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.

4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

What your screen should look like now

- The phase output and final validation are saved or visible.

- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 15.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 16 imports trusted tables, builds relationships, and defines DAX measures.

Phase 15 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Phase 16 — Build and validate the Power BI semantic model

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: A validated star-schema semantic model and measures.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 17 uses those governed fields to construct report pages and visual interactions.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 16 lesson index

1. [Lesson 16.1 — Understand the phase and starting screen](#)
2. [Lesson 16.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 16.3 — Create and understand the phase files](#)
4. [Lesson 16.4 — Build and validate required objects](#)
5. [Lesson 16.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 16.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Power BI Desktop, Power Query Editor, Model view, DAX formula bar, and SSMS.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 16 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 15 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 16 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Power BI Desktop, Power Query Editor, Model view, DAX formula bar, and SSMS. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 16 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 16 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 16 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 16.1 completion checklist

☐

I read why Phase 16 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 16.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 16 lesson index](#)

Lesson 16.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 16 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A Power BI semantic model over NorthstarRetail_DW with a proper date table, one-to-many single-direction relationships, hidden technical columns, documented business measures, useful hierarchies, display folders, and a Databricks SQL view alternative. This workbook supplies exact model documentation and optional reference DAX; you create and verify the .pbix yourself so the portfolio evidence is genuinely yours.

2. Why it matters

The semantic layer gives every report the same business definitions. Without it, two analysts can calculate revenue, returns, or conversion differently even when they read the same warehouse tables.

3. Words to know

Term	Plain-language definition
Semantic model	Reusable tables, relationships, measures, formats, and business definitions used by reports.
DAX	Data Analysis Expressions, the formula language used for Power BI measures and calculated objects.
Measure	A calculation evaluated under the current report filters, such as Total Revenue.
Filter context	The active filters from slicers, rows, columns, relationships, and visual selections.
Import	Power BI copies data into its in-memory model during refresh.
DirectQuery	Power BI sends queries to the source when a visual needs data.
Cardinality	How many matching rows can exist on each side of a relationship.
Cross-filter direction	The direction in which a filter travels through a relationship.
Date table	A complete one-row-per-date dimension used for time intelligence.
Explicit measure	A named DAX calculation rather than an automatic column aggregation.
Display folder	A model organization label for related measures.
Hierarchy	An ordered drill path, such as Year > Quarter > Month > Date.
Default summarization	Whether a numeric column is summed automatically; keys should normally be Do not summarize.
Databricks SQL view	A saved SQL query that presents business-friendly columns as an alternate semantic access path.

4. What must already be completed

Phase 15 is verified: NorthstarRetail_DW exists, semantic views query successfully, dimensions and facts reconcile to the selected Gold batch, and the account you will use can read the dw or semantic schema.

5. Applications to open

Application	How to open it	Why it is open
Power BI Desktop	Windows Start menu > search Power BI Desktop > Open.	Create the model and report file.
SSMS	Open from Start and connect to the verified local SQL Server.	Validate every measure against SQL.
VS Code	Open the repository and powerbi/ folder.	Read the model contract and copy reviewed DAX one measure at a time.
Databricks SQL editor	Workspace > SQL > SQL Editor, if your tier exposes it.	Create/query the optional semantic views.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run Get-Location; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
SELECT SUM(net_sales_amount) AS total_revenue,	Creates the unfiltered SQL baseline for three core measures.	The semantic model must reproduce warehouse truth before visual design begins.
Total Revenue =	Defines a reusable revenue measure that responds to report filters.	An explicit measure is documented and behaves consistently across visuals.
Gross Margin Percentage =	Calculates margin safely and returns blank when the denominator is zero.	DIVIDE handles zero/blank denominators more safely than /.
SELECT SUM(f.net_sales_amount) AS filtered_revenue	Builds a filter-matched validation query.	An all-data match does not prove relationships or filter context work.
SELECT order_date_key,	Provides a simple alternate semantic query path over Gold.	It demonstrates that the business definition is portable across serving tools.

Import versus DirectQuery decision

For the small local Track A portfolio, Import is the default: it is simpler, fast for interactive visuals, and does not require the local SQL Server to answer every click. DirectQuery keeps data at the source but adds source performance, concurrency, transformation, and feature considerations. Record the decision rather than calling one mode universally better.

Relationship rule

A dimension has one row per key/version and filters a fact with many rows. Start with single-direction dimension-to-fact relationships. Bidirectional filtering can solve specific designs but can also create multiple filter paths and ambiguous totals; do not enable it as a quick fix.

Required measures

powerbi/measures.dax contains Total Revenue, Gross Profit, Gross Margin Percentage, Promotion Gross Profit, Orders, Units Sold, Average Order Value, Return Rate, On-Time Delivery Percentage, Marketing Spend, Return on Ad Spend, Conversion Rate, New Customers, Returning Customers, Inventory On Hand, and Stockout Risk Count. Each measure includes a business explanation and SQL validation method.

MY TASK

Build the Power BI model yourself, create all required relationships and measures, validate every measure under at least one nontrivial filter, and capture model/validation evidence without publishing fabricated KPI values.

STARTER SKELETON

```
-- TODO(USER): type this only after defining the business rule.
Average Order Value =
DIVIDE (
    [Total Revenue],
    [Orders]
)

-- TODO(USER): validate the numerator and denominator separately in SQL.
-- TODO(USER): set format and description in Model view.
-- TODO(USER): record the filtered test in your learning journal.
```

Acceptance criteria: All 15 required tables load; relationships match the contract with no unexplained ambiguity; dim_date is marked; technical columns are hidden; every required measure has format, description, display folder, and SQL validation evidence; the saved PBIX is labeled as your own verified work.

HINT 1 — CONCEPT

A measure is only trustworthy when its table grain, relationship path, and denominator are understood.

HINT 2 — PSEUDOCODE

Create base measures first, validate them, then create ratios with DIVIDE and validate filtered cases.

HINT 3 — NEAR-COMPLETE PATTERN

Use powerbi/measures.dax and sql/sqlserver/analytics/kpi_validation_queries.sql; copy one measure, place it in a simple visual, match filters in SQL, and record the difference.

13. Expected files or output

- A local Northstar_Retail_Portfolio.pbix created by you.
- Model view screenshot showing the star-schema relationships.
- 15 documented DAX measures with correct formats.
- Measure validation table with SQL result, DAX result, difference, status, and filter definition.
- Optional Databricks SQL semantic-view/query evidence.

14. How to verify

- Every dimension key is unique on the one side.
- No relationship is many-to-many unless explicitly justified.
- Cross-filter direction is Single by default.
- Dates filter all applicable facts through the intended date key.
- Every unfiltered and filtered DAX result matches SQL within documented rounding tolerance.
- A zero-denominator case returns blank or the documented safe value.
- No technical ID is accidentally summed in a visual.

15. Automated tests

- SQL-to-DAX baseline tests for all measures.

- One-date, date-range, channel, store, product, and no-data filter tests.
- Relationship uniqueness query for each dimension key.
- Ambiguous-path inspection in Manage relationships.
- Refresh test after a controlled warehouse reload.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
The relationship cannot be created because a column contains duplicate values	The supposed dimension key is not unique or an SCD2 business key was used instead of surrogate key.	Run <code>GROUP BY key HAVING COUNT(*) > 1</code> in SSMS.	Use the dimension surrogate key on the one side and fix duplicate dimension grain upstream.	The duplicate query returns zero and relationship is 1:*
Power BI detected ambiguous relationships	Multiple active paths or bidirectional filters connect the same tables.	Open Manage relationships and trace every active path.	Return to single-direction star relationships; use inactive role-playing dates plus explicit DAX only when required.	No ambiguity warning and filtered totals match SQL.
Measure total looks wrong	Ratio/average was calculated row-by-row or an implicit aggregation was used.	Show numerator and denominator measures beside the total; run matching SQL.	Create explicit base measures and use DIVIDE at the intended grain.	Detail rows and grand total both match their SQL definitions.
Time intelligence is blank or inconsistent	Date table is not marked, dates are missing, or relationship uses the wrong date key.	Inspect min/max dates and missing dates in <code>dim_date</code> ; check relationship.	Use a complete date dimension, mark it, and activate the intended date relationship.	Date slicer and monthly totals match SQL.
Refresh cannot connect	Wrong server/database, SQL service stopped, or credentials changed.	Confirm SSMS connection with the same server and database.	Start the service, correct data source settings, and re-enter credentials through Power BI UI.	Refresh completes and row counts remain reconciled.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. Why is a semantic model more than a set of charts?
2. Why does filter context change a measure result?
3. Why is a surrogate key used in fact-to-dimension relationships?
4. When might DirectQuery be chosen instead of Import?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. Which cross-filter direction is the default for this star schema?
2. Why should Gross Margin Percentage use DIVIDE?
3. What must be identical between a DAX validation and its SQL query?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture Model view with all relationship lines, the marked date-table property, the Measures display folders, and one DAX-versus-SQL validation. Hide machine/user names and credentials.

Save the image under `docs/images/` with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: document and validate power bi semantic model
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Connected to NorthstarRetail_DW — [STATUS]

☐

15 model tables loaded — [STATUS]

☐

Relationships created and checked — [STATUS]

☐

Date table marked and hierarchy created — [STATUS]

☐

Technical columns hidden — [STATUS]

☐

All required DAX measures created — [STATUS]

☐

Filtered SQL validations passed — [STATUS]

☐

Model screenshot captured — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-16. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-16.

Next phase: Phase 17 turns the trusted semantic model into audience-specific report pages and analyst consumption examples.

Required action cards

Action 16.2.1 — Open powerbi/README.md, powerbi/semantic_model.md, and powerbi/measures.dax in VS Code. Read the table g

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Open powerbi/README.md, powerbi/semantic_model.md, and powerbi/measures.dax in VS Code. Read the table g. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open powerbi/README.md, powerbi/semantic_model.md, and powerbi/measures.dax in VS Code. Read the table grain and relationship table before opening Power BI.

4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 1****Action**

Open `powerbi/README.md`, `powerbi/semantic_model.md`, and `powerbi/measures.dax` in VS Code. Read the table grain and relationship table before opening Power BI.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

Action 16.2.2 — Open Power BI Desktop. On the welcome page choose ; if the welcome page is closed, use .

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Open Power BI Desktop. On the welcome page choose ; if the welcome page is closed, use . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open Power BI Desktop. On the welcome page choose **Get data**; if the welcome page is closed, use **Home > Get data > SQL Server**.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 2

Action

Open Power BI Desktop. On the welcome page choose **Get data**; if the welcome page is closed, use **Home > Get data > SQL Server**.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

Action 16.2.3 — Enter the exact local server name already verified in SSMS and database NorthstarRetail_DW. Choose for Track

Application:

SQL Server Management Studio (SSMS)

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Enter the exact local server name already verified in SSMS and database NorthstarRetail_DW. Choose for Track. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Enter the exact local server name already verified in SSMS and database Northstar-Retail_DW. Choose **Import** for Track A unless you have a measured reason to practice DirectQuery. Do not type a password into any repository file.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

SQL Server Management Studio (SSMS). When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 3

Action

Enter the exact local server name already verified in SSMS and database NorthstarRetail_DW. Choose **Import** for Track A unless you have a measured reason to practice DirectQuery. Do not type a password into any repository file.

Before continuing

☐

I used the application named in this phase.

[Back to the Phase 16 lesson index](#)

Action 16.2.4 — Choose the appropriate Windows or database authentication in the credential dialog. In Navigator select the ni

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Choose the appropriate Windows or database authentication in the credential dialog. In Navigator select the ni. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Choose the appropriate Windows or database authentication in the credential dialog. In Navigator select the nine dw.dim_* tables and six dw.fact_* tables. Select **Transform Data**, not Load, so you can inspect types first.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 4****Action**

Choose the appropriate Windows or database authentication in the credential dialog. In Navigator select the nine dw.dim_* tables and six dw.fact_* tables. Select **Transform Data**, not Load, so you can inspect types first.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

[Back to the Phase 16 lesson index](#)

Action 16.2.5 — In Power Query, inspect each query name, column type, row count preview, and error indicator. Do not add busin

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

In Power Query, inspect each query name, column type, row count preview, and error indicator. Do not add busin. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: In Power Query, inspect each query name, column type, row count preview, and error indicator. Do not add business calculations that belong in the warehouse or DAX. Rename only if the model contract documents the rename, then choose **Close & Apply**.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 5****Action**

In Power Query, inspect each query name, column type, row count preview, and error indicator. Do not add business calculations that belong in the warehouse or DAX. Rename only if the model contract documents the rename, then choose **Close & Apply**.

Before continuing☐

I used the application named in this phase.

Action 16.2.9 — Use to create a one-row table named `_Measures`, or use a documented existing table. Create each measure from

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Use to create a one-row table named `_Measures`, or use a documented existing table. Create each measure from . This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Use **Home > Enter data** to create a one-row table named `_Measures`, or use a documented existing table. Create each measure from `measures.dax` one at a time, then move it to the matching display folder.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 9

Action

Use **Home > Enter data** to create a one-row table named `_Measures`, or use a documented existing table. Create each measure from `measures.dax` one at a time, then move it to the matching display folder.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use `Back` or `Cancel` rather than `Delete` or `Overwrite`. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

Action 16.2.10 — Format currencies, whole numbers, percentages, and decimal precision exactly as documented. Do not use FORMAT()

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Format currencies, whole numbers, percentages, and decimal precision exactly as documented. Do not use FORMAT(). This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Format currencies, whole numbers, percentages, and decimal precision exactly as documented. Do not use FORMAT() merely for visual formatting because it changes a numeric result into text.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 10****Action**

Format currencies, whole numbers, percentages, and decimal precision exactly as documented. Do not use FORMAT() merely for visual formatting because it changes a numeric result into text.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

Action 16.2.11 — For every measure, run the corresponding SQL validation query in SSMS using the same date/channel/store filter

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

For every measure, run the corresponding SQL validation query in SSMS using the same date/channel/store filter. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: For every measure, run the corresponding SQL validation query in SSMS using the same date/channel/store filters. Record the DAX result, SQL result, difference, and status.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 11

Action

For every measure, run the corresponding SQL validation query in SSMS using the same date/channel/store filters. Record the DAX result, SQL result, difference, and status.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

Action 16.2.12 — Create a temporary matrix with date, channel, and product category to test totals under multiple filters. Test

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create a temporary matrix with date, channel, and product category to test totals under multiple filters. Test. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Create a temporary matrix with date, channel, and product category to test totals under multiple filters. Test an empty-selection case, one date, multiple dates, and all dates.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 12****Action**

Create a temporary matrix with date, channel, and product category to test totals under multiple filters. Test an empty-selection case, one date, multiple dates, and all dates.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

Action 16.2.13 — Save the model as Northstar_Retail_Portfolio.pbix in a local ignored folder. Add only screenshots and docume

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Save the model as Northstar_Retail_Portfolio.pbix in a local ignored folder. Add only screenshots and docume. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Save the model as Northstar_Retail_Portfolio.pbix in a local ignored folder. Add only screenshots and documentation to Git unless you intentionally decide to version the PBIX and understand its binary-file tradeoff.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 13

Action

Save the model as Northstar_Retail_Portfolio.pbix in a local ignored folder. Add only screenshots and documentation to Git unless you intentionally decide to version the PBIX and understand its binary-file tradeoff.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

Action 16.2.C1 — SSMS query window (SQL Server / T-SQL)

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window (SQL Server / T-SQL)

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT SUM(net_sales_amount) AS total_revenue,
       SUM(gross_profit_amount) AS gross_profit,
       COUNT(DISTINCT order_id) AS orders
FROM dw.fact_sales;
```

Where to enter it:

SSMS query window (SQL Server / T-SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT SUM(net_sales_amount) AS total_revenue,` — `SELECT` requests data without changing it unless combined with a modifying statement; `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `net_sales_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `total_revenue` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `SUM(gross_profit_amount) AS gross_profit,` — `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gross_profit_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gross_profit` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 3:** `COUNT(DISTINCT order_id) AS orders` — `COUNT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DISTINCT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `order_id` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `orders` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `FROM dw.fact_sales;` — `FROM` identifies the source table or query; `dw.fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.2.C2 — Power BI Desktop DAX formula bar

Application:

Power BI Desktop

Window or panel:

Power BI Desktop DAX formula bar

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Dax instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Power BI Desktop** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Dax):

```
Total Revenue =  
SUM ( fact_sales[net_sales_amount] )
```

Where to enter it:

Power BI Desktop DAX formula bar. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Total Revenue = — Total is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Revenue is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SUM (fact_sales[net_sales_amount]) — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; net_sales_amount is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

Action 16.2.C3 — Power BI Desktop DAX formula bar

Application:

Power BI Desktop

Window or panel:

Power BI Desktop DAX formula bar

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Dax instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Power BI Desktop** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Dax):

```
Gross Margin Percentage =  
DIVIDE ( [Gross Profit], [Total Revenue] )
```

Where to enter it:

Power BI Desktop DAX formula bar. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** Gross Margin Percentage = — Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Margin is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Percentage is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([Gross Profit], [Total Revenue]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Profit is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Total is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Revenue is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.2.C4 — SSMS query window (SQL Server / T-SQL)

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window (SQL Server / T-SQL)

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT SUM(f.net_sales_amount) AS filtered_revenue
FROM dw.fact_sales AS f
JOIN dw.dim_date AS d ON d.date_key = f.order_date_key
WHERE d.full_date >= '2025-01-01'
AND d.full_date < '2025-02-01';
```

Where to enter it:

SSMS query window (SQL Server / T-SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT SUM(f.net_sales_amount) AS filtered_revenue` — `SELECT` requests data without changing it unless combined with a modifying statement; `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.net_sales_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `filtered_revenue` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `FROM dw.fact_sales AS f` — `FROM` identifies the source table or query; `dw.fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `JOIN dw.dim_date AS d ON d.date_key = f.order_date_key` — `JOIN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `dw.dim_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d.date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.order_date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `WHERE d.full_date >= '2025-01-01'` — `WHERE` filters rows to those meeting a condition; `d.full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `>=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `'2025-01-01'` is a quoted literal; the quotation marks preserve spaces or mark text
- **Line 5:** `AND d.full_date < '2025-02-01'`; — `AND` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d.full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `<` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `'2025-02-01'` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.2.C5 — Databricks SQL editor (Databricks SQL / Spark SQL)

Application:

Databricks workspace in a web browser

Window or panel:

Databricks SQL editor (Databricks SQL / Spark SQL)

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Databricks workspace in a web browser** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT order_date_key,
       SUM(net_sales_amount) AS total_revenue,
       SUM(gross_profit_amount) AS gross_profit
FROM northstar_retail.gold.fact_sales
GROUP BY order_date_key
ORDER BY order_date_key;
```

Where to enter it:

Databricks SQL editor (Databricks SQL / Spark SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT order_date_key, —` `SELECT` requests data without changing it unless combined with a modifying statement; `order_date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `SUM(net_sales_amount) AS total_revenue, —` `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `net_sales_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `total_revenue` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `SUM(gross_profit_amount) AS gross_profit —` `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gross_profit_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gross_profit` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `FROM northstar_retail.gold.fact_sales —` `FROM` identifies the source table or query; `northstar_retail.gold.fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `GROUP BY order_date_key —` `GROUP` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `order_date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `ORDER BY order_date_key; —` `ORDER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `order_date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 16.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 16 starting-screen checklist and re-verify the active context.

Lesson 16.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 16 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — docs/

Exact folder name: docs

Exact parent: repository root

Why it is needed now: Phase 16 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: docs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 16.D1.1 — Create the folder docs

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\docs" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\docs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run Test-Path ".\docs" -PathType Container.
2. Require the output True before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — powerbi/

Exact folder name: powerbi

Exact parent: repository root

Why it is needed now: Phase 16 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: powerbi.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 16.D2.1 — Create the folder powerbi

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.

3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\powerbi" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\powerbi" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\powerbi"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm

the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Folder-creation decision branches

If the folder is created

Run `Test-Path -LiteralPath ".\powerbi" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\powerbi" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\powerbi" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — powerbi/semantic_model.md

Exact filename: `semantic_model.md`

Filename extension: `.md`. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `powerbi` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 16.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `powerbi` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `semantic_model.md`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `semantic_model.md` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 16.F1.1 — Create the file `powerbi/semantic_model.md` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\powerbi\semantic_model.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\powerbi\semantic_model.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\powerbi\semantic_model.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\powerbi\semantic_model.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "powerbi/semantic_model.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `powerbi`.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with powerbi/semantic_model.md.
3. In PowerShell at the repository root, run Test-Path ".\powerbi\semantic_model.md" and require True.
4. Run git status --short -- "powerbi/semantic_model.md" to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for powerbi/semantic_model.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: powerbi/semantic_model.md

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 16.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Power BI Semantic Model

## Model rule

Use a star schema. Every relationship normally filters from one dimension to one fact in a single direction. Avoid fact-to-fact relationships and bidirectional filtering unless you can explain and test the ambiguity it introduces.

## Relationships

| From dimension column | To fact column | Cardinality | Cross-filter | Active? |
|---|---|---|---|---|
| dim_date[date_key] | fact_sales[order_date_key] | One-to-many | Single | Yes |
| dim_date[date_key] | fact_returns[return_date_key] | One-to-many | Single | Yes |
| dim_date[date_key] | fact_inventory_snapshot[snapshot_date_key] | One-to-many | Single | Yes |
| dim_date[date_key] | fact_shipments[ship_date_key] | One-to-many | Single | Yes |
| dim_date[date_key] | fact_shipments[promised_date_key] | One-to-many | Single | No |
| dim_date[date_key] | fact_shipments[delivery_date_key] | One-to-many | Single | No |
| dim_date[date_key] | fact_web_sessions[session_date_key] | One-to-many | Single | Yes |
| dim_date[date_key] | fact_marketing_spend[spend_date_key] | One-to-many | Single | Yes |
| dim_customer[customer_key] | fact_sales[customer_key] | One-to-many | Single | Yes |
| dim_customer[customer_key] | fact_shipments[customer_key] | One-to-many | Single | Yes |
| dim_customer[customer_key] | fact_web_sessions[customer_key] | One-to-many | Single | Yes |
| dim_customer[customer_key] | fact_returns[customer_key] | One-to-many | Single | Yes |
| dim_product[product_key] | fact_sales[product_key] | One-to-many | Single | Yes |
| dim_product[product_key] | fact_returns[product_key] | One-to-many | Single | Yes |
| dim_product[product_key] | fact_inventory_snapshot[product_key] | One-to-many | Single | Yes |
| dim_employee[employee_key] | fact_sales[employee_key] | One-to-many | Single | Yes |
| dim_promotion[promotion_key] | fact_sales[promotion_key] | One-to-many | Single | Yes |
| dim_store[store_key] | sales/returns/inventory/shipments store_key | One-to-many | Single | Yes |
| dim_channel[channel_key] | sales/web_sessions/marketing_spend channel_key | One-to-many | Single | Yes |
| dim_campaign[campaign_key] | web_sessions/marketing_spend campaign_key | One-to-many | Single | Yes |
| dim_supplier[supplier_code] | dim_product[supplier_code] | One-to-many | Single | Yes – documented snowflake exception |

### Supplier relationship note

'dim_supplier' is the one documented snowflake exception in the beginner model because the required facts do not carry a supplier key. Supplier filters travel through 'dim_product'. Verify 'dim_supplier[supplier_code]' is unique, keep the relationship single-direction, and do not add a second supplier-to-fact path. A larger production model may denormalize supplier attributes into 'dim_product' or add supplier keys to appropriate procurement/inventory facts.

## Date table

In Model view, select 'dim_date', then **Table tools > Mark as date table > Mark as date table**, choose 'full_date', and confirm. Sort 'month_name' by 'month_number'. Create a hierarchy: 'calendar_year > quarter_number > month_name > full_date'.

## Hidden technical columns

Hide surrogate keys from report view after relationships are correct: all '*_key' columns, batch ID, record hash, load timestamp, source system, SCD effective dates unless an audit page needs them. Do not delete them from the model.

## Display folders and formats

- '_Measures\Sales': Total Revenue, Gross Profit, Gross Margin %, Promotion Gross Profit, Orders, Units Sold, Average Order Value.
- '_Measures>Returns and Shipping': Return Rate, On-Time Delivery %.
- '_Measures\Marketing': Marketing Spend, Attributed Revenue, Return on Ad Spend, Conversion Rate.
- '_Measures\Customer': Purchasing Customers, New Customers, Returning Customers.
- '_Measures\Inventory': Inventory On Hand, Stockout Risk Count.

Format money as currency with two decimals, counts as whole numbers with thousands separators, and rates as percentages with one or two decimals. Add the business definition from 'docs/kpi_definitions.md' to each measure's Description property.

## Import versus DirectQuery decision

Use **Import** for Track A: the local warehouse is modest, development is faster, and you can control refresh manually. DirectQuery is an advanced choice when near-real-time access, data volume, governance, and capacity justify the latency and modeling tradeoffs. Record the choice in 'docs/assumption_log.md'.
```

Attribution warning

The included `Attributed Revenue` measure uses converting session order IDs, equivalent to a simplified last-converting-session link. It is not a multi-touch causal model. Test that an order ID appears once before presenting ROAS.

File introduction — `powerbi/measures.dax`

Exact filename: `measures.dax`

Filename extension: `.dax`. In this project it identifies Power BI measures and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `powerbi` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: Power BI measures for Phase 16.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `powerbi` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `measures.dax`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `measures.dax` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

Action 16.F2.1 — Create the file `powerbi/measures.dax` from PowerShell

Application:

Power BI Desktop

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Power BI Desktop** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\powerbi\measures.dax" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\powerbi\measures.dax" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\powerbi\measures.dax"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\powerbi\measures.dax" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "powerbi/measures.dax"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `powerbi`.

2. Right-click the editor tab and choose **Copy Path**; compare the ending with `powerbi/measures.dax`.
3. In PowerShell at the repository root, run `Test-Path ".\powerbi\measures.dax"` and require `True`.
4. Run `git status --short -- "powerbi/measures.dax"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `powerbi/measures.dax`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: DAX

Exact file: `powerbi/measures.dax`

Purpose: Power BI measures.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 16.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
// Northstar Retail Power BI measures
// Put these in a dedicated empty table named _Measures.
// Replace column names only if your loaded warehouse schema differs.

- **Line 115:** `)` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

[Back to the Phase 16 lesson index](#)

File introduction — docs/kpi_definitions.csv

Exact filename: `kpi_definitions.csv`

Filename extension: `.csv`. In this project it identifies structured rows used as a definition, mapping, or fixture and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `docs` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: structured rows used as a definition, mapping, or fixture for Phase 16.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `docs` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `kpi_definitions.csv`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `kpi_definitions.csv` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

PowerShell path

Action 16.F3.1 — Create the file docs/kpi_definitions.csv from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\kpi_definitions.csv" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\docs\kpi_definitions.csv" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\docs\kpi_definitions.csv" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\docs\kpi_definitions.csv" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/kpi_definitions.csv"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under docs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/kpi_definitions.csv`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\kpi_definitions.csv"` and require `True`.
4. Run `git status --short -- "docs/kpi_definitions.csv"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

[Back to the Phase 16 lesson index](#)

What your screen should look like now

- Every Phase 16 file you actually created appears under the correct parent folder.
- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.

- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

Lesson 16.3 completion checklist

powerbi/semantic_model.md was created by me, saved, located correctly, and inspected — [STATUS]

powerbi/measures.dax was created by me, saved, located correctly, and inspected — [STATUS]

docs/kpi_definitions.csv was created by me, saved, located correctly, and inspected — [STATUS]

Safe stopping point

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 16.4](#) and recheck the root and branch.

Lesson 16.4 — Build and validate required objects

What your screen should look like before starting

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

Power BI measure 1 — Total Revenue

Business meaning: Net merchandise sales after line discounts, before subtracting cost; tax is excluded.

Business formula: `SUM(net_sales_amount)`

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: `fact_sales`

Important filters: Exclude cancelled/invalid lines upstream; selected date/channel/product/store filters apply.

Recommended format: Currency.

Action 16.4.M1 — Create, format, and validate the Total Revenue DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Total Revenue DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.

4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Total Revenue shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Total Revenue shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

DAX definition

```
Total Revenue =  
SUM ( fact_sales[net_sales_amount] )
```

Line-by-line DAX explanation

- **Line 1:** Total Revenue = — Total is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Revenue is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SUM (fact_sales[net_sales_amount]) — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; net_sales_amount is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare DAX card to SQL under the same date and slicer filters.

Common interpretation mistake: Adding tax or shipping without stating it, or summing order totals at line grain.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Total Revenue from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 2 — Gross Profit

Business meaning: Revenue remaining after cost of goods sold.

Business formula: SUM(net_sales_amount - cost_of_goods_sold)

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales

Important filters: Same population as revenue; USD-only in beginner track.

Recommended format: Currency.

Action 16.4.M2 — Create, format, and validate the Gross Profit DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Gross Profit DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Gross Profit shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Gross Profit shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

DAX definition

```
Gross Profit =
SUM ( fact_sales[gross_profit_amount] )
```

Line-by-line DAX explanation

- **Line 1:** Gross Profit = — Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Profit is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SUM (fact_sales[gross_profit_amount]) — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; gross_profit_amount is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Net revenue minus COGS must equal stored gross profit within rounding tolerance.

Common interpretation mistake: Treating gross profit as operating profit; marketing, payroll, and overhead are not included.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Gross Profit from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 3 — Gross Margin %

Business meaning: Gross profit as a share of revenue.

Business formula: Gross Profit / Total Revenue

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales

Important filters: Same filter context for numerator and denominator.

Recommended format: Percentage.

Action 16.4.M3 — Create, format, and validate the Gross Margin % DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Gross Margin % DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Gross Margin % shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Gross Margin % shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.

8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
Gross Margin % =
DIVIDE ( [Gross Profit], [Total Revenue] )
```

Line-by-line DAX explanation

- **Line 1:** Gross Margin % = — Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Margin is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([Gross Profit], [Total Revenue]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Profit is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Total is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Revenue is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Calculate from independently queried profit and revenue; do not average row margins.

Common interpretation mistake: Averaging product-level percentages instead of dividing aggregate amounts.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Gross Margin % from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 4 — Promotion Gross Profit

Business meaning: Gross profit contributed by accepted sales that used a known promotion. Use it to compare promotion contribution, not to claim causal incremental lift.

Business formula: SUM(gross_profit_amount) for promotion_key <> 0

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales[gross_profit_amount,promotion_key]; dim_promotion[promotion_key,promotion_name,promotion_code,start_date,end_date]

Important filters: Exclude unknown/no-promotion key 0; use the same accepted-sales, date, channel, and USD filters as Gross Profit.

Recommended format: Currency.

Action 16.4.M4 — Create, format, and validate the Promotion Gross Profit DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Promotion Gross Profit DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.

5. TYPE THIS: Enter the exact measure definition for Promotion Gross Profit shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Promotion Gross Profit shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
Promotion Gross Profit =  
CALCULATE (  
    [Gross Profit],  
    KEEPFILTERS ( dim_promotion[promotion_key] <> 0 )  
)
```

Line-by-line DAX explanation

- **Line 1:** Promotion Gross Profit = — Promotion is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Profit is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** CALCULATE (— CALCULATE evaluates an expression under modified DAX filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** [Gross Profit], — [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Gross is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Profit is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** KEEPFILTERS (dim_promotion[promotion_key] <> 0) — KEEPFILTERS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; dim_promotion is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; promotion_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; <> is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:**) —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the DAX measure by promotion to the grouped SQL result under identical dates, channels, and promotion filters.

Common interpretation mistake: Treating observed promoted-sales profit as incremental causal lift while ignoring baseline demand, cannibalization, and discount cost.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Promotion Gross Profit from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 5 — Orders

Business meaning: Distinct completed or shipped customer orders represented in sales.

Business formula: COUNT(DISTINCT order_id)

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales

Important filters: Invalid/cancelled orders excluded in Silver policy.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M5 — Create, format, and validate the Orders DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Orders DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Orders shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Orders shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.

11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

Interview-ready explanation

"I defined Orders from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 6 — Units Sold

Business meaning: Total valid product units on sales lines.

Business formula: SUM(quantity)

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales

Important filters: Quantity must be positive after Silver quarantine.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M6 — Create, format, and validate the Units Sold DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Units Sold DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Units Sold shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.

DAX definition

```
Units Sold =  
SUM ( fact_sales[quantity] )
```

Line-by-line DAX explanation

- **Line 1:** `Units Sold =` — `Units` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Sold` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 2:** `SUM ( fact_sales[quantity] )` — SUM adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `quantity` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Reconcile to valid Silver quantities.

Common interpretation mistake: Including returned units as negative sales without defining net units separately.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined `Units Sold` from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 7 — Average Order Value

Business meaning: Average net merchandise revenue per distinct order.

Business formula: Total Revenue / Orders

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: `fact_sales`

Important filters: Same context as revenue and orders.

Recommended format: Currency.

Action 16.4.M7 — Create, format, and validate the Average Order Value DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Average Order Value DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Average Order Value shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Average Order Value shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location

with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
Average Order Value =  
DIVIDE ( [Total Revenue], [Orders] )
```

Line-by-line DAX explanation

- **Line 1:** Average Order Value = — Average is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Order is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Value is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([Total Revenue], [Orders]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Total is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Revenue is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Orders is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Aggregate each order first and average, then compare.

Common interpretation mistake: Using average line revenue.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Average Order Value from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 8 — Returned Units

Business meaning: A governed semantic calculation used by one or more report pages.

Business formula: See the DAX expression and supporting measures below.

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: See expression dependencies and semantic model mapping.

Important filters: Use the documented date role and exclude invalid source rows upstream.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M8 — Create, format, and validate the Returned Units DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Returned Units DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Returned Units shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Returned Units shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

DAX definition

```
Returned Units =  
SUM ( fact_returns[return_quantity] )
```

Line-by-line DAX explanation

- **Line 1:** Returned Units = — Returned is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Units is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SUM (fact_returns[return_quantity]) — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_returns is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; return_quantity is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the measure with an independently filtered SQL query at the same grain and date context.

Common interpretation mistake: Using a different denominator, date role, or filter population than the documented business definition.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Returned Units from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 9 — Return Rate

Business meaning: Returned units divided by sold units for a comparable filtered population.

Business formula: $\text{SUM}(\text{return_quantity}) / \text{SUM}(\text{sold quantity})$

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_returns, fact_sales, shared dimensions

Important filters: Use compatible date definition; report purchase-date or return-date view explicitly.

Recommended format: Percentage.

Action 16.4.M9 — Create, format, and validate the Return Rate DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Return Rate DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Return Rate shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.

4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Return Rate shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

DAX definition

```
Return Rate =
DIVIDE ( [Returned Units], [Units Sold] )
```

Line-by-line DAX explanation

- **Line 1:** Return Rate = — Return is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Rate is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([Returned Units], [Units Sold]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Returned is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Units is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Units is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Sold is a name, keyword, argument, identifier, or literal

whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Trace a small product/date sample from sales to returns.

Common interpretation mistake: Dividing return rows by order rows, or mixing return-date and purchase-date contexts silently.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Return Rate from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 10 — Delivered Shipments

Business meaning: A governed semantic calculation used by one or more report pages.

Business formula: See the DAX expression and supporting measures below.

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: See expression dependencies and semantic model mapping.

Important filters: Use the documented date role and exclude invalid source rows upstream.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M10 — Create, format, and validate the Delivered Shipments DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Delivered Shipments DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

DAX definition

```
On-Time Shipments =  
CALCULATE (  
    [Delivered Shipments],  
    fact_shipments[on_time_flag] = TRUE ()  
)
```

Line-by-line DAX explanation

- **Line 1:** On-Time Shipments = — On-Time is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Shipments is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** CALCULATE (— CALCULATE evaluates an expression under modified DAX filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** [Delivered Shipments], — [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Delivered is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Shipments is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** fact_shipments[on_time_flag] = TRUE () — fact_shipments is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; on_time_flag is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; TRUE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

planation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 5:**) —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the measure with an independently filtered SQL query at the same grain and date context.

Common interpretation mistake: Using a different denominator, date role, or filter population than the documented business definition.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined On-Time Shipments from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 12 — On-Time Delivery %

Business meaning: Share of delivered shipments whose actual delivery date is on or before promised date.

Business formula: On-time shipments / delivered shipments

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_shipments

Important filters: Delivered shipments with a non-null actual date only.

Recommended format: Percentage.

Action 16.4.M12 — Create, format, and validate the On-Time Delivery % DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the On-Time Delivery % DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.

3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for On-Time Delivery % shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for On-Time Delivery % shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
On-Time Delivery % =  
DIVIDE ( [On-Time Shipments], [Delivered Shipments] )
```

Line-by-line DAX explanation

- **Line 1:** On-Time Delivery % = — On-Time is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Delivery is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([On-Time Shipments], [Delivered Shipments]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; On-Time is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Shipments is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Delivered is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Shipments is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Manually inspect promised and actual dates for a sample.

Common interpretation mistake: Using orders as denominator when one order can have multiple shipments.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined On-Time Delivery % from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 13 — Marketing Spend

Business meaning: Recorded media spend in the governed reporting currency.

Business formula: SUM(spend_amount)

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_marketing_spend

Important filters: USD only in Track A; date and campaign filters apply.

Recommended format: Currency.

Action 16.4.M13 — Create, format, and validate the Marketing Spend DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Marketing Spend DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Marketing Spend shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

DAX definition

```
Marketing Spend =  
SUM ( fact_marketing_spend[spend_amount] )
```

Line-by-line DAX explanation

- **Line 1:** Marketing Spend = — Marketing is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Spend is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SUM (fact_marketing_spend[spend_amount]) — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_marketing_spend is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; spend_amount is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Reconcile to accepted Silver spend rows.

Common interpretation mistake: Mixing currencies or campaign budgets with actual spend.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Marketing Spend from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 14 — Web Sessions

Business meaning: A governed semantic calculation used by one or more report pages.

Business formula: See the DAX expression and supporting measures below.

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: See expression dependencies and semantic model mapping.

Important filters: Use the documented date role and exclude invalid source rows upstream.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M14 — Create, format, and validate the Web Sessions DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Web Sessions DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Web Sessions shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

DAX definition

```
Web Sessions =  
SUM ( fact_web_sessions[session_count] )
```

Line-by-line DAX explanation

- **Line 1:** `Web Sessions =` — `Web` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `SUM ( fact_web_sessions[session_count] )` — `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `fact_web_sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described

in the surrounding explanation; session_count is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the measure with an independently filtered SQL query at the same grain and date context.

Common interpretation mistake: Using a different denominator, date role, or filter population than the documented business definition.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Web Sessions from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 15 — Converted Sessions

Business meaning: A governed semantic calculation used by one or more report pages.

Business formula: See the DAX expression and supporting measures below.

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: See expression dependencies and semantic model mapping.

Important filters: Use the documented date role and exclude invalid source rows upstream.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M15 — Create, format, and validate the Converted Sessions DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Converted Sessions DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.

3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Converted Sessions shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

DAX definition

```
Converted Sessions =  
CALCULATE (  
    [Web Sessions],  
    fact_web_sessions[converted_flag] = TRUE ()  
)
```

Line-by-line DAX explanation

- **Line 1:** `Converted Sessions =` — `Converted` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `CALCULATE (` — `CALCULATE` evaluates an expression under modified DAX filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `[Web Sessions],` — `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Web` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `fact_web_sessions[converted_flag] = TRUE ()` — `fact_web_sessions` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `[` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `converted_flag` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `]` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TRUE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `()` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `)` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the measure with an independently filtered SQL query at the same grain and date context.

Common interpretation mistake: Using a different denominator, date role, or filter population than the documented business definition.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined `Converted Sessions` from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 16 — Conversion Rate

Business meaning: Share of web sessions that are linked to a completed order.

Business formula: `Converted sessions / sessions`

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use

compatible populations.

Required tables/columns: fact_web_sessions

Important filters: Bot traffic is out of scope; filter by session date/channel/campaign.

Recommended format: Percentage.

Action 16.4.M16 — Create, format, and validate the Conversion Rate DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Conversion Rate DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Conversion Rate shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Conversion Rate shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.

11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
Conversion Rate =  
DIVIDE ( [Converted Sessions], [Web Sessions] )
```

Line-by-line DAX explanation

- **Line 1:** Conversion Rate = — Conversion is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Rate is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([Converted Sessions], [Web Sessions]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Converted is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Sessions is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;], is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Web is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Sessions is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare converted session count to non-null converted_order_id values.

Common interpretation mistake: Dividing orders by page views or users without labeling the denominator.

- Power BI filter/slicer state: [ENTER]

- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Conversion Rate from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 17 — Attributed Revenue

Business meaning: A governed semantic calculation used by one or more report pages.

Business formula: See the DAX expression and supporting measures below.

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: See expression dependencies and semantic model mapping.

Important filters: Use the documented date role and exclude invalid source rows upstream.

Recommended format: Currency.

Action 16.4.M17 — Create, format, and validate the Attributed Revenue DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Attributed Revenue DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Attributed Revenue shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for `Attributed Revenue` shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

- **Line 11:** `)` — `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the measure with an independently filtered SQL query at the same grain and date context.

Common interpretation mistake: Using a different denominator, date role, or filter population than the documented business definition.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Attributed Revenue from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 18 — Return on Ad Spend

Business meaning: Attributed sales revenue divided by marketing spend under a stated attribution model.

Business formula: Attributed Revenue / Marketing Spend

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_web_sessions, fact_sales, fact_marketing_spend, dim_campaign

Important filters: Beginner model uses last converting session; exclude unattributed revenue from numerator.

Recommended format: Percentage.

Action 16.4.M18 — Create, format, and validate the Return on Ad Spend DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Return on Ad Spend DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Return on Ad Spend shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.

8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Return on Ad Spend shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
Return on Ad Spend =  
DIVIDE ( [Attributed Revenue], [Marketing Spend] )
```

Line-by-line DAX explanation

- **Line 1:** Return on Ad Spend = — Return is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; on is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Ad is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Spend is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** DIVIDE ([Attributed Revenue], [Marketing Spend]) — DIVIDE performs protected division in DAX; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Attributed is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Revenue is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] , is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Marketing is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Spend is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: List converted order IDs and verify each is counted once before comparing spend.

Common interpretation mistake: Calling total company revenue campaign-attributed revenue.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Return on Ad Spend from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 19 — Purchasing Customers

Business meaning: A governed semantic calculation used by one or more report pages.

Business formula: See the DAX expression and supporting measures below.

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: See expression dependencies and semantic model mapping.

Important filters: Use the documented date role and exclude invalid source rows upstream.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M19 — Create, format, and validate the Purchasing Customers DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Purchasing Customers DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Purchasing Customers shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Purchasing Customers shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

DAX definition

```
Purchasing Customers =  
CALCULATE (  
    DISTINCTCOUNT ( fact_sales[customer_key] ),  
    fact_sales[customer_key] <> 0  
)
```

Line-by-line DAX explanation

- **Line 1:** Purchasing Customers = — Purchasing is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Customers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** CALCULATE (— CALCULATE evaluates an expression under modified DAX filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** DISTINCTCOUNT (fact_sales[customer_key]), — DISTINCTCOUNT is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; customer_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;), is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** fact_sales[customer_key] <> 0 — fact_sales is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; customer_key is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; <> is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; 0 is a numeric literal used by the command or expression
- **Line 5:**) —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Compare the measure with an independently filtered SQL query at the same grain and date context.

Common interpretation mistake: Using a different denominator, date role, or filter population than the documented business definition.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Purchasing Customers from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 20 — New Customers

Business meaning: Customers whose first completed purchase occurs in the selected period.

Business formula: Distinct customers with first order date in period

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales, dim_date

Important filters: Selected reporting period; unknown customer excluded.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M20 — Create, format, and validate the New Customers DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the New Customers DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for New Customers shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.

9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for New Customers shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

SQL/DAX validation

Validation method: Compare a list of customer first-order dates between SQL and Power BI.

Common interpretation mistake: Using signup date when the business question is first purchase.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined New Customers from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 21 — Returning Customers

Business meaning: Customers purchasing in the period whose first purchase occurred before the period.

Business formula: Purchasing customers - New Customers

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_sales, dim_date

Important filters: Selected reporting period; unknown customer excluded.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M21 — Create, format, and validate the Returning Customers DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Returning Customers DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Returning Customers shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Returning Customers shown below.
6. PRESS: Enter.

7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

DAX definition

```
Returning Customers =
[Purchasing Customers] - [New Customers]
```

Line-by-line DAX explanation

- **Line 1:** Returning Customers = — Returning is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Customers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** [Purchasing Customers] - [New Customers] — [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Purchasing is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Customers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; - is a command option or flag; its exact behavior is defined beside the command; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; New is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Customers is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Pick customers around the period boundary and inspect order history.

Common interpretation mistake: Counting repeated orders rather than distinct customers.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Returning Customers from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 22 — Inventory On Hand

Business meaning: Physical quantity recorded at the selected snapshot date.

Business formula: SUM(quantity_on_hand)

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_inventory_snapshot

Important filters: A single snapshot date is usually required; do not sum across dates.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M22 — Create, format, and validate the Inventory On Hand DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Inventory On Hand DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated _Measures table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Inventory On Hand shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.

8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Inventory On Hand shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

DAX definition

```
Inventory On Hand =  
SUM ( fact_inventory_snapshot[quantity_on_hand] )
```

Line-by-line DAX explanation

- **Line 1:** Inventory On Hand = — Inventory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; On is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Hand is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** SUM (fact_inventory_snapshot[quantity_on_hand]) — SUM adds numeric values in the current filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_inventory_snapshot is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; quantity_on_hand is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Check one date/store/product against the source snapshot.

Common interpretation mistake: Summing inventory over multiple dates, which double-counts stock.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]
- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Inventory On Hand from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

Power BI measure 23 — Stockout Risk Count

Business meaning: Count of store-product snapshot rows at or below their reorder threshold.

Business formula: COUNTROWS where stockout_risk_flag = 1

Filter context: Slicers and relationships change the rows visible to the expression; numerator and denominator must use compatible populations.

Required tables/columns: fact_inventory_snapshot

Important filters: Use latest or selected snapshot date.

Recommended format: Whole number or appropriate numeric format.

Action 16.4.M23 — Create, format, and validate the Stockout Risk Count DAX measure

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Create, format, and validate the Stockout Risk Count DAX measure. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Stockout Risk Count shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

1. CLICK: Open Power BI Desktop and select **Model view** or **Report view**.
2. CLICK: In the Fields/Data pane, select the dedicated `_Measures` table.
3. CLICK: On the ribbon, select **New measure**.
4. LOOK FOR: Confirm the DAX formula bar appears and begins with a default measure name.
5. TYPE THIS: Enter the exact measure definition for Stockout Risk Count shown below.
6. PRESS: Enter.
7. CLICK: Select the measure and set its format: currency, whole number, decimal, or percentage as defined by the KPI.
8. CLICK: Assign the measure to the appropriate display folder when the model uses display folders.
9. CLICK: Add a temporary card or table visual with the measure and the same filters used by the SQL validation query.
10. PRESS: Run the independent SQL query in SSMS.
11. LOOK FOR: Compare Power BI and SQL values at full precision before display rounding.
12. DO NOT CONTINUE UNTIL: The values agree or every difference is explained and corrected.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 16 lesson index](#)

DAX definition

```
Stockout Risk Count =
CALCULATE (
    COUNTROWS ( fact_inventory_snapshot ),
    fact_inventory_snapshot[stockout_risk_flag] = TRUE ()
)
```

Line-by-line DAX explanation

- **Line 1:** Stockout Risk Count = — Stockout is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Risk is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; Count is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** CALCULATE (— CALCULATE evaluates an expression under modified DAX filter context; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** COUNTROWS (fact_inventory_snapshot), — COUNTROWS is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; fact_inventory_snapshot is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;), is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** fact_inventory_snapshot[stockout_risk_flag] = TRUE () — fact_inventory_snapshot is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; [is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; stockout_risk_flag is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation;] is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; = is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; TRUE is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; () is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:**) —) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

SQL/DAX validation

Validation method: Recompute available quantity <= reorder point for a sample.

Common interpretation mistake: Calling a low-stock warning an actual stockout without distinguishing zero inventory.

- Power BI filter/slicer state: [ENTER]
- SQL WHERE conditions: [ENTER]
- SQL result before formatting: [ENTER]
- DAX result before display rounding: [ENTER]
- Difference: [ENTER]

- Status: [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

Common error and exact recovery

If Power BI and SQL differ, first compare date role, relationship direction, hidden filters, null/unknown keys, distinct-count grain, and numerator/denominator populations. Do not rewrite the DAX until the comparison query matches the semantic definition.

Interview-ready explanation

"I defined Stockout Risk Count from a documented business formula, used reusable base measures where appropriate, formatted it explicitly, and validated it against SQL under identical filters rather than trusting the visual alone."

What your screen should look like now

- The new Phase 16 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

Lesson 16.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 16.5](#).

Lesson 16.5 — Verify, troubleshoot, commit, teach back, and stop safely

What your screen should look like before starting

The Phase 16 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

Design decision — Power BI Import versus DirectQuery

Question:

How should Power BI access the local dimensional warehouse?

Options considered:

- Import.
- DirectQuery.
- Composite model.

Beginner path selected:

Use Import for the required beginner model.

Why this path was selected:

It is responsive, supports the full modeling experience, and suits the synthetic batch volume.

Tradeoff:

Refresh is required to see new warehouse data.

What a company might do instead:

Companies choose by latency, scale, governance, gateway, and semantic-model requirements.

How to explain this in an interview:

I selected Import because the project is batch-oriented and small; I validated refresh totals against SQL and documented DirectQuery tradeoffs.

If you see Result A

Relationships have the intended cardinality/direction and DAX matches filtered SQL. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

If you see Result B

Power BI proposes an ambiguous or many-to-many relationship, or a measure differs under the same filter. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

If you see an error

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

Phase-specific verification gate

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

☐

Actual verified result: [ENTER VERIFIED RESULT].

Point-of-failure troubleshooting record

Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

What it means in plain language:

[WRITE YOUR INTERPRETATION]

Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

Safest fix:

[ENTER THE NARROW FIX]

Alternative fix when applicable:

[ENTER OR N/A]

How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

Screenshot checkpoint

Application(s) that should be visible: Power BI Desktop, Power Query Editor, Model view, DAX formula bar, and SSMS.

Window/panel: Show Power BI model view, relationship settings, DAX measure, and matching SQL result.

Sensitive information to hide: Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

Include: The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

Crop out: Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

Recommended filename: docs/images/phase16_build-and-validate-the-power-bi-semantic-model_verified.png.

Recommended repository folder: docs/images/.

README placement: The section describing Phase 16's verified result; do not use the image before the result is actually verified.

What it proves: The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

Git checkpoint after the verified Phase 16 changes

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

Action 16.5.G1 — Verify the repository root before Git operations

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.5.G2 — Verify the active Git branch

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git branch --show-current
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.5.G3 — Inspect all current Git changes

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git status --short
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Interpret git status --short

- ?? means untracked: Git sees a new path but it is not staged.
- M means modified in the working tree but not staged.
- M means the staged version differs from the last commit.
- MM means a staged version exists and the file has additional unstaged edits.
- A means staged as a new file.
- D means deletion; stop and investigate unless deletion is deliberate.
- R means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

Action 16.5.G4 — Inspect the unstaged diff for powerbi/semantic_model.md

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.

6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff -- "powerbi/semantic_model.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff -- "powerbi/semantic_model.md"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"powerbi/semantic_model.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.5.G5 — Stage only the reviewed file powerbi/semantic_model.md

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git add -- "powerbi/semantic_model.md"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git add -- "powerbi/semantic_model.md"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"powerbi/semantic_model.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

Action 16.5.G6 — Inspect the staged diff

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.

4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git diff --cached
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.5.G7 — Create the Phase 16 commit

Application:

Power BI Desktop

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Power BI Desktop** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git commit -m "feat: build validated power bi semantic model"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git commit -m "feat: build validated power bi semantic model"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: build validated power bi semantic model"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Action 16.5.G8 — Verify the new commit

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git log -1 --oneline --decorate
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

Action 16.5.G9 — Push the feature branch and set upstream

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
git push -u origin "$(git branch --show-current)"
```

Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 16 lesson index](#)

Verify on GitHub

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: build validated power bi semantic model and the intended changed paths`.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

Explain it in your own words

Without copying the model answer, explain:

1. What you created or configured in Phase 16.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.

9. Which decision/tradeoff you could defend in an interview.

My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

OPTIONAL REFERENCE ANSWER — PHASE 16 TEACH-BACK MODEL

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

"Phase 16 created the verified boundary described by **Build and validate the Power BI semantic model**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed."

Mini quiz

1. Multiple choice: Why does Phase 16 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
 2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
 3. Fill in the blank: The statement that defines what one row represents is the table or entity _____.
 4. What command would you use first to confirm the PowerShell current folder before a repository command?
 5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
 6. Design choice: Explain one tradeoff of Track A and one production alternative.
 7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
 8. Ownership: Which status may you select only after personally performing and inspecting the verification?
-

Mini quiz answer key and explanations

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.
5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** `PLANNED`, `CREATED BY USER`, and `RUN BY USER` describe earlier states; only inspected evidence supports verification.

[WRITE YOUR ANSWER]

What I still need to practice:

[WRITE YOUR ANSWER]

What your screen should look like now

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

Lesson 16.5 completion checklist

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

Safe stopping point

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

How this phase connects to the next phase

Phase 17 uses those governed fields to construct report pages and visual interactions.

Phase 16 completion checklist

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

Phase 17 — Build and validate all Power BI report pages

[Back to the master table of contents](#)

Track: Track A required

Status when first opened: PLANNED

Completion rule: The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

Why this phase happens now

Earlier work this phase depends on: Accurate report pages and SQL-to-DAX validation evidence.

What would go wrong if it happened earlier: You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

Later work that depends on it: Phase 18 reviews every location where secrets, compute cost, or sensitive data can appear.

Decision being made: Choose and verify the simplest local-first method that teaches the professional concept without pretending that local services are publicly reachable.

Alternatives: A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

Beginner path selected: Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

Reason for the order: Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

Phase 17 lesson index

1. [Lesson 17.1 — Understand the phase and starting screen](#)
2. [Lesson 17.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 17.3 — Create and understand the phase files](#)
4. [Lesson 17.4 — Build and validate required objects](#)
5. [Lesson 17.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

Lesson 17.1 — Understand the phase and starting screen

What your screen should look like before starting

- **Application open:** Power BI Desktop Report view, Format pane, Selection pane, and SSMS validation windows.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 17 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 16 must be verified when this phase has a prerequisite.

Three-level explanation of the phase

Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

Level 2 — Northstar Retail project explanation

Phase 17 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

Applications to open

Power BI Desktop Report view, Format pane, Selection pane, and SSMS validation windows. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

Phase status gate

☐

I changed this phase from [] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

What your screen should look like now

- The Phase 17 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.

- No new Phase 17 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 17 master-tracker row is marked [-] In progress only after you personally updated it.

Lesson 17.1 completion checklist

☐

I read why Phase 17 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

Safe stopping point

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 17.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 17 lesson index](#)

Lesson 17.2 — Perform the notebook-guided actions one at a time

What your screen should look like before starting

The Phase 17 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

Retained phase lesson, exercises, rules, and expected results

Track: Track A required

Ownership status at start: Workbook instructions exist; your execution is not yet verified.

Evidence rule: Replace placeholders only after the verification steps pass.

1. What you are building

A nine-page Power BI report design, an executive KPI view, a data-quality monitoring page, a dashboard wireframe, drill-through plan, validation checklist, and at least 20 analyst SQL questions with query skeletons. You populate visuals only from your verified model and label incomplete pages honestly.

2. Why it matters

A technically correct platform has value only when people can answer business questions safely. Consumption design connects each audience, question, metric, filter, visual, and validation rule.

3. Words to know

Term	Plain-language definition
Consumption layer	The reports, SQL queries, exports, or applications through which people use trusted data.
KPI card	A visual displaying one important measure, often with period context or target.
Slicer	A report control that changes filter context.

Term	Plain-language definition
Drill-through	Navigation from a summary item to a detail page filtered to that item.
Tooltip page	A report page shown when a user hovers over a visual data point.
Wireframe	A layout plan showing where visuals and controls belong without claiming real results.
Executive view	A compact view of outcomes, changes, risks, and decisions rather than operational detail.
Operational view	A detailed view used to act on current process conditions.
Misleading chart	A visual whose scale, aggregation, category count, or encoding can cause a false interpretation.
Accessibility	Design that remains usable with keyboard navigation, readable text, adequate contrast, and meaningful labels.

4. What must already be completed

The Phase 16 semantic model is verified and saved. Every measure used by a report page has a business definition and at least one SQL validation.

5. Applications to open

Application	How to open it	Why it is open
Power BI Desktop	Open your verified PBIX.	Build and test report pages.
SSMS	Connect to NorthstarRetail_DW.	Run analyst and visual-validation queries.
VS Code	Open powerbi/dashboard_requirements.md and the SQL analytics folder.	Follow the report contract and record evidence.
Web browser	Open the local HTML notebook/GitHub preview after screenshots are added.	Review portfolio presentation without publishing private details.

6. Exact click-by-click steps

Beginner rhythm: Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

7. Exact commands, one code block at a time

8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

Line-by-line code explanation

Line or action	Meaning	Why it belongs here
SELECT TOP (20)	Returns the daily series used to validate a trend visual.	A chart should be checked at its displayed grain, not only as a grand total.
SELECT p.category_name,	Creates the category comparison baseline.	It verifies relationship filtering and category grouping.
Get-Content .\sql\sqlserver\analytics\20_analyst_questions.sql Select-String '^-- [0-9][0-9].'	Lists the analyst question headings included in the reference file.	You should know the scope before attempting queries.
python -m scripts.validation.validate_markdown_links	Checks report documentation links and screenshot placeholders resolve.	Portfolio navigation is part of the consumption experience.

Page contract

Each page in `powerbi/dashboard_requirements.md` states audience, business question, measures, dimensions, slicers, recommended visuals, drill-through, SQL validation, and a common misleading alternative. A visual is not selected because it looks impressive; it is selected because its encoding fits the question.

Do not fabricate results

Wireframes may contain labels such as `[TOTAL REVENUE]` but not invented numbers. After your pipeline runs, replace placeholders only with values visible in a validated model and capture the data-through date and batch evidence.

MY TASK

Build and validate the nine report pages, complete at least 20 analyst questions, add one useful drill-through path, and create screenshots that prove your own execution without exposing credentials or inventing performance claims.

STARTER SKELETON

```
PAGE: Inventory
AUDIENCE: TODO(USER)
DECISION: TODO(USER)
GRAIN SHOWN: TODO(USER)
MEASURES: Inventory On Hand; Stockout Risk Count
DIMENSIONS: TODO(USER)
SLICERS: TODO(USER)
VISUALS: TODO(USER)
DRILL-THROUGH: TODO(USER)
SQL VALIDATION: TODO(USER)
MISLEADING CHOICE TO AVOID: TODO(USER)
SCREENSHOT FILE: docs/images/TODO_USER_inventory_page.png
```

Acceptance criteria: All nine pages have a documented audience and question; every visible KPI uses an explicit validated measure; interactions and drill-through work; each critical visual matches a same-grain SQL query; accessibility checks are recorded; screenshots show only real verified results or clearly marked placeholders.

HINT 1 — CONCEPT

Start with the decision and grain, then choose the visual.

HINT 2 — PSEUDOCODE

For each visual: identify measure, grouping columns, filters, and SQL GROUP BY; compare the resulting rows.

HINT 3 — NEAR-COMPLETE PATTERN

Use the page contracts, add a table visual temporarily, match it to the provided SQL patterns, then replace it with the final visual after validation.

13. Expected files or output

- Nine named Power BI pages.
- One drill-through flow and useful tooltip behavior.
- Executive KPI and data-quality monitoring views.
- At least 20 attempted analyst queries with notes.
- Completed screenshot checklist and evidence files.
- A wireframe that contains no fabricated numbers.

14. How to verify

- Every page answers its stated business question.
- All visual grains and filters are documented.
- No implicit measures are used for published KPIs.
- Critical chart table views match SQL.
- Slicer interactions and synced slicers are intentional.

- Drill-through retains the correct context.
- Data-quality page exposes failed/quarantined checks rather than hiding them.
- Screenshots include a verified data-through context.

15. Automated tests

- Visual-to-SQL same-grain comparisons.
- Slicer interaction matrix.
- Drill-through context test.
- Empty/no-data state test.
- Accessibility/tab-order/alt-text review.
- Screenshot privacy and truthfulness review.

16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
A chart changes when an unrelated slicer is used	Synced slicer or visual interaction is broader than intended.	Use Edit interactions and inspect Sync slicers.	Disable the invalid interaction or redesign the page contract.	Only intended visuals change.
Grand total differs from the sum of visible percentages	The measure is recalculated in total filter context, which is often correct for ratios.	Display numerator/denominator at row and total levels.	Explain the ratio behavior; do not sum percentages unless the business rule truly requires it.	Total matches the SQL ratio definition.
Too many categories are unreadable	A categorical visual is overloaded.	Count distinct categories and inspect audience need.	Use Top N with an explicit Other/selection path, a table, or drill-through; disclose the filter.	All omitted categories remain accessible and no hidden bias is introduced.
Map or region visual is blank/wrong	Geographic category is ambiguous or unsupported.	Inspect data category, country/state fields, and null/invalid codes.	Set correct data category and use a bar/matrix if geography cannot be resolved safely.	Locations or alternative visual match source counts.
Screenshot shows a result that later changes	Refresh batch or filters were not recorded.	Check batch/load timestamp and active filters.	Capture a data-through date and evidence note; replace stale screenshots after a material change.	Screenshot and evidence point to the same run.

For deeper tool-specific diagnosis, use [the troubleshooting index near the end of this workbook](#).

17. Explain it in your own words

1. How does the audience change the amount of detail on a page?
2. Why should a visual be validated at its displayed grain?
3. Why can a grand-total percentage correctly differ from the sum of row percentages?
4. What makes a dashboard screenshot trustworthy?

Write your answers in the learning-journal fields in this phase. Do not copy the wording above.

18. Mini quiz

1. What should be defined before choosing a visual?
2. Which page must expose quality failures and quarantine counts?
3. What is the safest response when a page is not yet verified?

Record your answers before opening the answer key.

19. Screenshot checkpoint

Capture each completed report page, one drill-through result, one Edit interactions view, and one SQL-to-visual validation. Use the Phase 17 in-workbook checklist; do not show fabricated numbers.

Save the image under docs/images/ with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

20. Git checkpoint and suggested commit message

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
feat: add validated consumption layer design and evidence
```

Push the feature branch only after tests pass.

21. Completion checklist

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

Executive Overview complete — [STATUS]

☐

Sales/Product/Store/Customer pages complete — [STATUS]

☐

Marketing/Inventory/Shipping pages complete — [STATUS]

☐

Data Quality page complete — [STATUS]

☐

Drill-through and interactions tested — [STATUS]

☐

20 analyst queries attempted — [STATUS]

☐

Visual-to-SQL checks passed — [STATUS]

☐

Screenshots reviewed and saved — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: the optional reference-answer section later in this workbook#phase-17. The quiz answer is in the answer-key section immediately after the quiz in this workbook#phase-17.

Next phase: Phase 18 protects configuration, credentials, access, logs, and cost while keeping the synthetic portfolio safe to publish.

Required action cards

Action 17.2.1 — Read `powerbi/dashboard_requirements.md`. For each page, write the audience and one decision the page should s

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Read `powerbi/dashboard_requirements.md`. For each page, write the audience and one decision the page should s. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Read `powerbi/dashboard_requirements.md`. For each page, write the audience and one decision the page should support before adding a visual.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 1****Action**

Read `powerbi/dashboard_requirements.md`. For each page, write the audience and one decision the page should support before adding a visual.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.2 — In Power BI Report view, rename the first page . Open and choose Fit to page while designing.

Application:

Power BI Desktop

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

In Power BI Report view, rename the first page . Open and choose Fit to page while designing. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: In Power BI Report view, rename the first page **Executive Overview**. Open **View > Page view** and choose Fit to page while designing.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 2

Action

In Power BI Report view, rename the first page **Executive Overview**. Open **View > Page view** and choose Fit to page while designing.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.3 — Add a horizontal date slicer and channel/store slicers that apply only where useful. Use intentionally; do not

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Add a horizontal date slicer and channel/store slicers that apply only where useful. Use intentionally; do not. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.

3. Perform only this immediate task: Add a horizontal date slicer and channel/store slicers that apply only where useful. Use **View > Sync slicers** intentionally; do not make every slicer global without testing.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 3****Action**

Add a horizontal date slicer and channel/store slicers that apply only where useful. Use **View > Sync slicers** intentionally; do not make every slicer global without testing.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.4 — Add KPI cards for revenue, gross profit, gross margin, orders, average order value, return rate, on-time deliv

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Add KPI cards for revenue, gross profit, gross margin, orders, average order value, return rate, on-time deliv. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Add KPI cards for revenue, gross profit, gross margin, orders, average order value, return rate, on-time delivery, and stockout risk. Add a visible "Data through" date sourced from the model.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 4

Action

Add KPI cards for revenue, gross profit, gross margin, orders, average order value, return rate, on-time delivery, and stockout risk. Add a visible "Data through" date sourced from the model.

Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.5 — Add a monthly revenue/profit trend and category/store comparison. Use consistent units and zero baselines wher

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Add a monthly revenue/profit trend and category/store comparison. Use consistent units and zero baselines wher. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Add a monthly revenue/profit trend and category/store comparison. Use consistent units and zero baselines where a bar length represents magnitude.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 5****Action**

Add a monthly revenue/profit trend and category/store comparison. Use consistent units and zero baselines where a bar length represents magnitude.

Before continuing☐

You can point to the visible result and explain what it proves. Mark the action `VERIFIED BY USER` only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.13 — Use the Phase 17 screenshot checkpoints in this workbook and the screenshot checkpoints in this workbook.

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Use the Phase 17 screenshot checkpoints in this workbook and the screenshot checkpoints in this workbook. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Use the Phase 17 screenshot checkpoints in this workbook and the screenshot checkpoints in this workbook. Capture only verified pages; use placeholder boxes in README for pages not yet built.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:

Step 13

Action

Use the Phase 17 screenshot checkpoints in this workbook and the screenshot checkpoints in this workbook. Capture only verified pages; use placeholder boxes in README for pages not yet built.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.14 — Do not publish a public report unless you understand tenant settings, sharing permissions, synthetic-data labe

Application:

Visual Studio Code

Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Do not publish a public report unless you understand tenant settings, sharing permissions, synthetic-data labe. This is one bounded construction or inspection task.

Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Do not publish a public report unless you understand tenant settings, sharing permissions, synthetic-data labeling, and account visibility. A PBIX plus screenshots is sufficient for the local-first portfolio.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

Where to enter it:

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

What each part means:**Step 14****Action**

Do not publish a public report unless you understand tenant settings, sharing permissions, synthetic-data labeling, and account visibility. A PBIX plus screenshots is sufficient for the local-first portfolio.

Before continuing☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

Action 17.2.C1 — SSMS query window (SQL Server / T-SQL)

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window (SQL Server / T-SQL)

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```
SELECT TOP (20)
    d.full_date,
    SUM(f.net_sales_amount) AS total_revenue,
    SUM(f.gross_profit_amount) AS gross_profit
FROM dw.fact_sales AS f
JOIN dw.dim_date AS d ON d.date_key = f.order_date_key
GROUP BY d.full_date
ORDER BY d.full_date DESC;
```

Where to enter it:

SSMS query window (SQL Server / T-SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** SELECT TOP (20) — SELECT requests data without changing it unless combined with a modifying statement; TOP is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; (is a name, keyword, argument, identifier, or literal whose project-specific role is described in the

surrounding explanation; 20 is a numeric literal used by the command or expression;) is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

- **Line 2:** `d.full_date, — d.full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `SUM(f.net_sales_amount) AS total_revenue, — SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.net_sales_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `total_revenue` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `SUM(f.gross_profit_amount) AS gross_profit — SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.gross_profit_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gross_profit` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `FROM dw.fact_sales AS f — FROM` identifies the source table or query; `dw.fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `JOIN dw.dim_date AS d ON d.date_key = f.order_date_key — JOIN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `dw.dim_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d.date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.order_date_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `GROUP BY d.full_date — GROUP` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d.full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 8:** `ORDER BY d.full_date DESC; — ORDER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `d.full_date` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DESC` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row

count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

Action 17.2.C2 — SSMS query window (SQL Server / T-SQL)

Application:

SQL Server Management Studio (SSMS)

Window or panel:

SSMS query window (SQL Server / T-SQL)

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Sql instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Sql):

```

SELECT p.category_name,
       SUM(f.net_sales_amount) AS revenue,
       SUM(f.gross_profit_amount) AS gross_profit
FROM dw.fact_sales AS f
JOIN dw.dim_product AS p ON p.product_key = f.product_key
GROUP BY p.category_name
ORDER BY revenue DESC;

```

Where to enter it:

SSMS query window (SQL Server / T-SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `SELECT p.category_name,` — `SELECT` requests data without changing it unless combined with a modifying statement; `p.category_name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `SUM(f.net_sales_amount) AS revenue,` — `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.net_sales_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `revenue` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `,` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `SUM(f.gross_profit_amount) AS gross_profit` — `SUM` adds numeric values in the current filter context; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.gross_profit_amount` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `gross_profit` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `FROM dw.fact_sales AS f` — `FROM` identifies the source table or query; `dw.fact_sales` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `JOIN dw.dim_product AS p ON p.product_key = f.product_key` — `JOIN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `dw.dim_product` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `AS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `p` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `p.product_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `=` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `f.product_key` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 6:** `GROUP BY p.category_name` — `GROUP` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `p.category_name` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 7:** `ORDER BY revenue DESC;` — `ORDER` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `BY` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `revenue` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DESC` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

Action 17.2.C3 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
Get-Content .\sql\sqlserver\analytics\20_analyst_questions.sql | Select-String '^-- [0-9][0-9]\.'
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `Get-Content .\sql\sqlserver\analytics\20_analyst_questions.sql | Select-String '^-- [0-9][0-9]\.'`
 — `Get-Content` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `sql` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `sqlserver` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `analytics` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `20_analyst_questions.sql` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `Select-String` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `'^-- [0-9][0-9]\.'` is a path, relative location, branch-style name, or file argument; verify every character before running it

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

Action 17.2.C4 — Windows PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

Windows PowerShell

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (Powershell):

```
python -m scripts.validation.validate_markdown_links
```

Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `python -m scripts.validation.validate_markdown_links` — python invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.validation.validate_markdown_links` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This is intended to inspect or validate state rather than change it.

Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

Lesson 17.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

I stopped at the first unexplained error — [STATUS]

Safe stopping point

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 17 starting-screen checklist and re-verify the active context.

Lesson 17.3 — Create and understand the phase files

What your screen should look like before starting

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 17 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

Folder introduction — powerbi/

Exact folder name: powerbi

Exact parent: repository root

Why it is needed now: Phase 17 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: powerbi.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method

Action 17.D1.1 — Create the folder powerbi

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\powerbi" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\powerbi" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\powerbi"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

Folder-creation decision branches**If the folder is created**

Run `Test-Path -LiteralPath ".\powerbi" -PathType Container` and require `True`.

If PowerShell says the folder already exists

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\powerbi" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\powerbi" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

Folder introduction — sql/

Exact folder name: `sql`

Exact parent: `repository root`

Why it is needed now: Phase 17 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

What will eventually be inside: Only files whose purpose matches this folder's name.

Why another folder is not appropriate: Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

Naming rules: Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `repository root` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `sql`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

PowerShell method**Action 17.D2.1 — Create the folder `sql`**

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\sql\sqlserver\analytics" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

If the parent path does not exist

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

Verify the folder

1. Run `Test-Path ".\sql\sqlserver\analytics" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

File introduction — `powerbi/dashboard_requirements.md`

Exact filename: `dashboard_requirements.md`

Filename extension: `.md`. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

Exact parent folder: `powerbi` relative to the repository root.

Why this file belongs there: Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

What the file will contain: project documentation for Phase 17.

Later dependencies: Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

Should Git track it? Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

Could it contain secrets? It should not contain live passwords, tokens, connection strings, or account identifiers.

What happens if it is missing: The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `powerbi` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `dashboard_requirements.md`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `dashboard_requirements.md` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

PowerShell path

Action 17.F1.1 — Create the file `powerbi/dashboard_requirements.md` from PowerShell

Application:

Windows PowerShell or the VS Code PowerShell terminal

Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

Current folder or location:

The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\powerbi\dashboard_requirements.md" -ErrorAction Stop
```

Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\powerbi\dashboard_requirements.md" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\powerbi\dashboard_requirements.md" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

Does it change anything?

This can change files, Git state, packages, database objects, or data.

Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

File-creation decision branches**If the command creates the file**

Run `Test-Path -LiteralPath ".\powerbi\dashboard_requirements.md" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "powerbi/dashboard_requirements.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

File verification

1. In the VS Code Explorer, confirm the file appears under `powerbi`.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `powerbi/dashboard_requirements.md`.
3. In PowerShell at the repository root, run `Test-Path ".\powerbi\dashboard_requirements.md"` and require `True`.
4. Run `git status --short -- "powerbi/dashboard_requirements.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

Optional reference answer for `powerbi/dashboard_requirements.md`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

Language: Markdown

Exact file: powerbi/dashboard_requirements.md

Purpose: project documentation.

Inputs: The requirements, configuration, source data, or upstream objects described in Phase 17.

Expected outputs: The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
# Power BI Report Requirements
```

No actual performance values are included. Replace every placeholder only after running and validating your pipeline.

```
| Page | Audience | Business question | Fields/KPIs | Slicers | Visuals | Drill-through | Validation | Misleading choice to avoid |
| --- | --- | --- | --- | --- | --- | --- | --- | --- |
| Executive Overview | Executives | Are revenue, profit, orders, delivery, and returns on track? | Revenue, gross profit, margin, orders, AOV, return rate, on-time delivery; monthly trend; channel mix | Date, region, channel | KPI cards, line chart, decomposition or bar chart | Sales Performance | Validate every KPI card to SQL; verify date slicer affects all visuals | Do not use a pie chart with many categories or a truncated trend axis. |
| Sales Performance | Sales leadership | Where are sales and profit growing or declining? | Revenue/profit by month, channel, store, region; order and AOV trends | Date, channel, region, store | Lines, clustered bars, matrix, waterfall for change | Order detail or Store and Region | Check totals and drill rows against semantic.vw_sales_detail | Do not mix revenue and margin percentages on one unlabeled axis. |
| Product and Category | Merchandising | Which products and categories drive profitable demand? | Revenue, units, gross profit, margin, discount by SKU/category | Date, category, brand, supplier | Treemap only for high-level mix, bars, scatter price vs margin, matrix | Product detail | Validate top N against analyst query 07 | Top revenue is not automatically top profit. |
| Store and Region | Retail operations | Which stores and regions outperform after accounting for volume? | Revenue, profit, orders, AOV, return rate by store/region | Date, region, store | Map only if location quality is verified; bars and matrix preferred | Store detail | Compare a selected store to SQL query 03 | Avoid maps that imply area size equals performance. |
| Customer | CRM and Leadership | How many new and returning customers buy, and how do segments behave? | New/returning, purchasing customers, revenue by tier/state | Date, loyalty tier, state | Cards, cohort-style matrix, bars | Customer history | Inspect first purchase dates for sample customers | Do not label signup as acquisition unless business definition says so. |
| Marketing Funnel | Marketing | Which channels and campaigns create efficient, attributable conversion? | Spend, sessions, conversion, attributed revenue, ROAS | Date, channel, campaign, device | Funnel, scatter spend vs revenue, campaign table | Campaign detail | Verify converted order IDs are unique before ROAS | Correlation and last-touch attribution are not causation. |
| Inventory | Inventory operations | Which store-product combinations are at stockout risk? | On hand, available, inventory value, risk count | Snapshot date, region, store, category | Cards, heatmap/matrix, ranked bars | Product-store detail | Use one snapshot date; recompute risk formula | Never sum snapshot stock across dates. |
| Shipping and Returns | Operations and CX | Where are delivery delays and returns concentrated? | On-time %, delivery days, returned units, return rate, refund amount | Ship/return date, carrier, region, reason | Cards, bars, distribution, matrix | Shipment/order detail | Sample promised vs actual dates and returned lines | Do not compare shipment count directly with order count without split-shipment context. |
| Data Quality | Data engineering and owners | Can decision-makers trust the latest batch? | Pass/fail, quarantines, unknown keys, freshness, reconciliation differences | Batch, date, source, rule | Status cards, rule table, trend | Batch detail | Compare to quality.test_results and audit.reconciliation_result | A green dashboard is meaningless if failed tests were filtered out. |
```

```
**Exact filename:** `20 analyst questions.sql`
```

```

**Filename extension:** `.sql`. In this project it identifies database or lakehouse definitions and queries and helps the correct application
choose syntax highlighting or execution behavior.
**Exact parent folder:** `sql/sqlserver/analytics` relative to the repository root.
**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transforma-
tions, tests, documentation, and report assets without guessing.
**What the file will contain:** database or lakehouse definitions and queries for Phase 17.
**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence
may depend on its exact path.
**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific arti-
fact.
**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.
**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

#### VS Code click path

1. CLICK: In VS Code, open Explorer from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `sql/sqlserver/analytics` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select New File.
7. TYPE THIS: `20_analyst_questions.sql`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `20_analyst_questions.sql` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

#### PowerShell path

<a id="action-17-f2-1"></a>
Action 17.F2.1 – Create the file `sql/sqlserver/analytics/20_analyst_questions.sql` from PowerShell

Application:
Windows PowerShell or the VS Code PowerShell terminal

Window or panel:
VS Code integrated PowerShell terminal opened at the repository root

Starting condition:
The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, cata-
log, schema, table, or file is the correct one.

Current folder or location:
The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named
in the action.

What you are about to do:
Run one explained PowerShell instruction and inspect its result before any next command is introduced.

Why this action comes now:
The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by
later output.

Exact physical actions:

1. CLICK: Bring Windows PowerShell or the VS Code PowerShell terminal to the front.
2. LOOK FOR: Confirm the current location matches `The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and
the open Power BI Desktop project/model view named in the action.` or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press Enter for a one-line terminal command, F5/Execute for the named database editor, or the notebook cell Run control as
stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

Command or code (PowerShell):

```powershell
New-Item -ItemType File -Path ".\sql\sqlserver\analytics\20_analyst_questions.sql" -ErrorAction Stop

```

### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\analytics\20_analyst_questions.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `.`

`\sql\sqlserver\analytics\20_analyst_questions.sql` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### **Does it change anything?**

This can change files, Git state, packages, database objects, or data.

### **Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### **What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### **Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### **What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### **How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### **Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### **Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

### **Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

### **What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

### **How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

## **File-creation decision branches**

### **If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\sqlserver\analytics\20_analyst_questions.sql" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

### **If PowerShell says the file already exists**

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/analytics/20_analyst_questions.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

### **If PowerShell says part of the path does not exist**

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

## File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under sql/sqlserver/analytics.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with sql/sqlserver/analytics/20\_analyst\_questions.sql.
3. In PowerShell at the repository root, run Test-Path ".\sql\sqlserver\analytics\20\_analyst\_questions.sql" and require True.
4. Run git status --short -- "sql/sqlserver/analytics/20\_analyst\_questions.sql" to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for sql/sqlserver/analytics/20\_analyst\_questions.sql

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** SQL

**Exact file:** sql/sqlserver/analytics/20\_analyst\_questions.sql

**Purpose:** database or lakehouse definitions and queries.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 17.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

## File introduction — `sql/sqlserver/analytics/kpi_validation_queries.sql`

**Exact filename:** `kpi_validation_queries.sql`

**Filename extension:** `.sql`. In this project it identifies database or lakehouse definitions and queries and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** `sql/sqlserver/analytics` relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** database or lakehouse definitions and queries for Phase 17.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

### VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `sql/sqlserver/analytics` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.

6. CLICK: Select **New File**.
7. TYPE THIS: `kpi_validation_queries.sql`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `kpi_validation_queries.sql` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

## PowerShell path

### Action 17.F3.1 — Create the file `sql/sqlserver/analytics/kpi_validation_queries.sql` from PowerShell

#### Application:

Windows PowerShell or the VS Code PowerShell terminal

#### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

#### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

#### Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

#### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

#### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

#### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

#### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\sql\sqlserver\analytics\kpi_validation_queries.sql" -ErrorAction Stop
```

#### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

#### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

#### What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\sql\sqlserver\analytics\kpi_validation_queries.sql" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\sql\sqlserver\analytics\kpi_validation_queries.sql"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined

beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### **Does it change anything?**

This can change files, Git state, packages, database objects, or data.

### **Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### **What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### **Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### **What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### **How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### **Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### **Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

### **Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

### **What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

### **How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

## **File-creation decision branches**

### **If the command creates the file**

Run `Test-Path -LiteralPath ".\sql\sqlserver\analytics\kpi_validation_queries.sql" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

### **If PowerShell says the file already exists**

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "sql/sqlserver/analytics/kpi_validation_queries.sql"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

### **If PowerShell says part of the path does not exist**

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

## **File-content construction**

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.

3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under sql/sqlserver/analytics.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with sql/sqlserver/analytics/kpi\_validation\_queries.sql.
3. In PowerShell at the repository root, run Test-Path ".\sql\sqlserver\analytics\kpi\_validation\_queries.sql" and require True.
4. Run git status --short -- "sql/sqlserver/analytics/kpi\_validation\_queries.sql" to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for sql/sqlserver/analytics/kpi\_validation\_queries.sql

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** SQL

**Exact file:** sql/sqlserver/analytics/kpi\_validation\_queries.sql

**Purpose:** database or lakehouse definitions and queries.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 17.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

[Back to the Phase 17 lesson index](#)

## What your screen should look like now

- Every Phase 17 file you actually created appears under the correct parent folder.

- Your open editor tab matches the file you are validating.
- The Git branch has not changed unexpectedly.
- `git status --short` lists only expected work.
- Reference answers remain reference material; your status fields are not automatically completed.

## Lesson 17.3 completion checklist

---

☐

powerbi/dashboard\_requirements.md was created by me, saved, located correctly, and inspected — [STATUS]

☐

sql/sqlserver/analytics/20\_analyst\_questions.sql was created by me, saved, located correctly, and inspected — [STATUS]

☐

sql/sqlserver/analytics/kpi\_validation\_queries.sql was created by me, saved, located correctly, and inspected — [STATUS]

## Safe stopping point

---

Save every open file with Ctrl+S. You may close VS Code only after `git status --short` is recorded in your journal. The terminal may be closed when no installer, transaction, Python process, Databricks run, warehouse load, or Power BI refresh is active. Resume at [Lesson 17.4](#) and recheck the root and branch.

## Lesson 17.4 — Build and validate required objects

---

### What your screen should look like before starting

---

The phase files are saved, the correct application and connection are visible, and the upstream input has passed its verification gate. Build one object at a time; do not create many objects and inspect them only at the end.

### Report page 1 — Executive Overview

**Audience and decision:** This page groups the measures and dimensions needed for a reader to answer the page's named business question without mixing incompatible grains.

**Required fields/measures:**

- Total Revenue
- Gross Profit
- Gross Margin %
- Orders
- Average Order Value
- On-Time Delivery %

**Page-size rule:** Use the documented canvas and keep consistent margins, alignment, reading order, and title placement.

**Slicer rule:** Date plus only the relevant dimensions. A slicer must not imply that it filters a measure when no valid relationship exists.

**Validation rule:** Every KPI and chart total is compared to a table visual and an independently filtered SQL query.

**Misleading alternatives to avoid:** Truncated axes without a reason, pie charts with too many categories, averaging row-level percentages, dual axes that suggest false correlation, totals across snapshot dates, and colors used as the only status signal.

## Action 17.4.P1 — Build and validate the Executive Overview report page

---

**Application:**

Power BI Desktop

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Build and validate the Executive Overview report page. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Executive Overview.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:**

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Executive Overview.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.

14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

#### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

#### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

#### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

#### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

#### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

#### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

#### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

#### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

#### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

### Literal visual build worksheet

Visual order	Visual type	Field placement	Aggregation/measure	Formatting	Interaction check	My verified result
1	Page title/text box	Executive Overview	none	consistent title size	n/a	[ENTER]
2	KPI cards	headline measures above	explicit measures only	units/decimals/percent	all page slicers	[ENTER]
3	Primary chart	page-specific date/category axis	explicit measure	title, labels, sort	test each slicer	[ENTER]
4	Secondary comparison	appropriate dimension	explicit measure	avoid misleading axis	test cross-highlight	[ENTER]
5	Detail table/matrix	keys hidden; readable attributes	measures	totals/subtotals deliberate	drill/tooltip check	[ENTER]
6	Slicers	date and relevant dimensions	no implicit aggregation	dropdown/list/range	inspect every visual	[ENTER]

#### Screenshot checkpoint

- **Application:** Power BI Desktop.
- **Window:** Report view with Executive Overview selected and the Filters pane showing no accidental hidden filter.
- **Include:** Page title, all visuals, current slicer state, and one visible validation element if readable.
- **Hide:** Server names beyond local examples, Windows username when unnecessary, account email, tokens, passwords, and unrelated desktop content.
- **Crop out:** Other applications and empty desktop area.
- **Recommended filename:** docs/images/phase17\_01\_executive-overview\_verified.png.

- **README placement:** Dashboard/report-pages section after the architecture and validation sections.
- **What it proves:** The verified page existed with the shown filter state; it does not prove every other filter combination.

## Interview-ready explanation

"I built the Executive Overview page from governed measures, set interactions deliberately, avoided grain/denominator traps, and reconciled displayed values to SQL under matching filters before using the screenshot as portfolio evidence."

## Report page 2 — Sales Performance

**Audience and decision:** This page groups the measures and dimensions needed for a reader to answer the page's named business question without mixing incompatible grains.

### Required fields/measures:

- Total Revenue
- Orders
- Units Sold
- Average Order Value
- dim\_date
- dim\_channel

**Page-size rule:** Use the documented canvas and keep consistent margins, alignment, reading order, and title placement.

**Slicer rule:** Date plus only the relevant dimensions. A slicer must not imply that it filters a measure when no valid relationship exists.

**Validation rule:** Every KPI and chart total is compared to a table visual and an independently filtered SQL query.

**Misleading alternatives to avoid:** Truncated axes without a reason, pie charts with too many categories, averaging row-level percentages, dual axes that suggest false correlation, totals across snapshot dates, and colors used as the only status signal.

## Action 17.4.P2 — Build and validate the Sales Performance report page

### Application:

Power BI Desktop

### Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

### Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

### What you are about to do:

Build and validate the Sales Performance report page. This is one bounded construction or inspection task.

### Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

#### Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

#### What each part means:

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Store and Region.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

#### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

#### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

#### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Literal visual build worksheet

Visual order	Visual type	Field placement	Aggregation/measure	Formatting	Interaction check	My verified result
1	Page title/text box	Store and Region	none	consistent title size	n/a	[ENTER]
2	KPI cards	headline measures above	explicit measures only	units/decimals/percent	all page slicers	[ENTER]
3	Primary chart	page-specific date/category axis	explicit measure	title, labels, sort	test each slicer	[ENTER]
4	Secondary comparison	appropriate dimension	explicit measure	avoid misleading axis	test cross-highlight	[ENTER]
5	Detail table/matrix	keys hidden; readable attributes	measures	totals/subtotals deliberate	drill/tooltip check	[ENTER]
6	Slicers	date and relevant dimensions	no implicit aggregation	dropdown/list/range	inspect every visual	[ENTER]

### Screenshot checkpoint

- **Application:** Power BI Desktop.
- **Window:** Report view with Store and Region selected and the Filters pane showing no accidental hidden filter.
- **Include:** Page title, all visuals, current slicer state, and one visible validation element if readable.
- **Hide:** Server names beyond local examples, Windows username when unnecessary, account email, tokens, passwords, and unrelated desktop content.
- **Crop out:** Other applications and empty desktop area.
- **Recommended filename:** docs/images/phase17\_04\_store-and-region\_verified.png.
- **README placement:** Dashboard/report-pages section after the architecture and validation sections.
- **What it proves:** The verified page existed with the shown filter state; it does not prove every other filter combination.

### Interview-ready explanation

"I built the Store and Region page from governed measures, set interactions deliberately, avoided grain/denominator traps, and reconciled displayed values to SQL under matching filters before using the screenshot as portfolio evidence."

## Report page 5 — Customer

**Audience and decision:** This page groups the measures and dimensions needed for a reader to answer the page's named business question without mixing incompatible grains.

### Required fields/measures:

- New Customers
- Returning Customers
- Purchasing Customers
- dim\_customer

**Page-size rule:** Use the documented canvas and keep consistent margins, alignment, reading order, and title placement.  
**Slicer rule:** Date plus only the relevant dimensions. A slicer must not imply that it filters a measure when no valid relationship exists.  
**Validation rule:** Every KPI and chart total is compared to a table visual and an independently filtered SQL query.  
**Misleading alternatives to avoid:** Truncated axes without a reason, pie charts with too many categories, averaging row-level percentages, dual axes that suggest false correlation, totals across snapshot dates, and colors used as the only status signal.

## Action 17.4.P5 — Build and validate the Customer report page

---

### Application:

Power BI Desktop

### Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

### Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

### What you are about to do:

Build and validate the Customer report page. This is one bounded construction or inspection task.

### Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

### Exact physical actions:

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Customer.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

### Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

### Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

### What each part means:

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.

2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Customer.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

### Interview-ready explanation

"I built the Customer page from governed measures, set interactions deliberately, avoided grain/denominator traps, and reconciled displayed values to SQL under matching filters before using the screenshot as portfolio evidence."

## Report page 6 — Marketing Funnel

**Audience and decision:** This page groups the measures and dimensions needed for a reader to answer the page's named business question without mixing incompatible grains.

**Required fields/measures:**

- Marketing Spend
- Web Sessions
- Converted Sessions
- Conversion Rate
- Return on Ad Spend
- dim\_campaign

**Page-size rule:** Use the documented canvas and keep consistent margins, alignment, reading order, and title placement.

**Slicer rule:** Date plus only the relevant dimensions. A slicer must not imply that it filters a measure when no valid relationship exists.

**Validation rule:** Every KPI and chart total is compared to a table visual and an independently filtered SQL query.

**Misleading alternatives to avoid:** Truncated axes without a reason, pie charts with too many categories, averaging row-level percentages, dual axes that suggest false correlation, totals across snapshot dates, and colors used as the only status signal.

## Action 17.4.P6 — Build and validate the Marketing Funnel report page

---

**Application:**

Power BI Desktop

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Build and validate the Marketing Funnel report page. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Marketing Funnel.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.

### Interview-ready explanation

"I built the Inventory page from governed measures, set interactions deliberately, avoided grain/denominator traps, and reconciled displayed values to SQL under matching filters before using the screenshot as portfolio evidence."

## Report page 8 — Shipping and Returns

**Audience and decision:** This page groups the measures and dimensions needed for a reader to answer the page's named business question without mixing incompatible grains.

### Required fields/measures:

- On-Time Delivery %
- Delivered Shipments
- Return Rate
- Returned Units
- dim\_date

**Page-size rule:** Use the documented canvas and keep consistent margins, alignment, reading order, and title placement.

**Slicer rule:** Date plus only the relevant dimensions. A slicer must not imply that it filters a measure when no valid relationship exists.

**Validation rule:** Every KPI and chart total is compared to a table visual and an independently filtered SQL query.

**Misleading alternatives to avoid:** Truncated axes without a reason, pie charts with too many categories, averaging row-level percentages, dual axes that suggest false correlation, totals across snapshot dates, and colors used as the only status signal.

## Action 17.4.P8 — Build and validate the Shipping and Returns report page

### Application:

Power BI Desktop

### Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

### Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

### What you are about to do:

Build and validate the Shipping and Returns report page. This is one bounded construction or inspection task.

### Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

### Exact physical actions:

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Shipping and Returns.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.

10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

#### Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

#### Where to enter it:

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

#### What each part means:

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Shipping and Returns.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

#### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

#### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

#### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

#### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

#### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 17 lesson index](#)

**Literal visual build worksheet**

Visual order	Visual type	Field placement	Aggregation/measure	Formatting	Interaction check	My verified result
1	Page title/text box	Shipping and Returns	none	consistent title size	n/a	[ENTER]
2	KPI cards	headline measures above	explicit measures only	units/decimals/percent	all page slicers	[ENTER]
3	Primary chart	page-specific date/category axis	explicit measure	title, labels, sort	test each slicer	[ENTER]
4	Secondary comparison	appropriate dimension	explicit measure	avoid misleading axis	test cross-highlight	[ENTER]
5	Detail table/matrix	keys hidden; readable attributes	measures	totals/subtotals deliberate	drill/tooltip check	[ENTER]
6	Slicers	date and relevant dimensions	no implicit aggregation	dropdown/list/range	inspect every visual	[ENTER]

**Screenshot checkpoint**

- **Application:** Power BI Desktop.
- **Window:** Report view with Shipping and Returns selected and the Filters pane showing no accidental hidden filter.
- **Include:** Page title, all visuals, current slicer state, and one visible validation element if readable.
- **Hide:** Server names beyond local examples, Windows username when unnecessary, account email, tokens, passwords, and unrelated desktop content.
- **Crop out:** Other applications and empty desktop area.
- **Recommended filename:** docs/images/phase17\_08\_shipping-and-returns\_verified.png.
- **README placement:** Dashboard/report-pages section after the architecture and validation sections.
- **What it proves:** The verified page existed with the shown filter state; it does not prove every other filter combination.

**Interview-ready explanation**

"I built the Shipping and Returns page from governed measures, set interactions deliberately, avoided grain/denominator traps, and reconciled displayed values to SQL under matching filters before using the screenshot as portfolio evidence."

**Report page 9 — Data Quality**

**Audience and decision:** This page groups the measures and dimensions needed for a reader to answer the page's named business question without mixing incompatible grains.

**Required fields/measures:**

- quality result status
- rule ID
- actual value
- expected value
- batch ID
- layer/entity

**Page-size rule:** Use the documented canvas and keep consistent margins, alignment, reading order, and title placement.

**Slicer rule:** Date plus only the relevant dimensions. A slicer must not imply that it filters a measure when no valid relationship exists.

**Validation rule:** Every KPI and chart total is compared to a table visual and an independently filtered SQL query.

**Misleading alternatives to avoid:** Truncated axes without a reason, pie charts with too many categories, averaging row-level percentages, dual axes that suggest false correlation, totals across snapshot dates, and colors used as the only status signal.

## Action 17.4.P9 — Build and validate the Data Quality report page

---

**Application:**

Power BI Desktop

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Build and validate the Data Quality report page. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Data Quality.
4. PRESS: Enter.
5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:**

1. CLICK: In Power BI Desktop Report view, select the + icon to create a blank page.
2. RIGHT-CLICK: Right-click the new page tab and select **Rename page**.
3. TYPE THIS: Data Quality.
4. PRESS: Enter.

5. CLICK: With the page selected, open the Format pane and set the documented page/canvas size; use a standard 16:9 canvas unless the requirement says otherwise.
6. CLICK: Add each visual one at a time; after adding a visual, select its fields before adding another.
7. CLICK: Add KPI/card visuals for the page's headline measures.
8. CLICK: Add the primary trend or comparison chart and assign the documented axis, values, legend, and tooltips.
9. CLICK: Add slicers for date and the page-specific dimensions; choose dropdown/list/between behavior deliberately.
10. CLICK: Format titles, display units, decimal places, percentage symbols, labels, and accessibility alt text.
11. CLICK: Open **Edit interactions** and test how every slicer affects every visual; disable only interactions that are intentionally misleading.
12. CLICK: Add a report-page tooltip or drill-through target only where the requirement calls for it, then test Back navigation.
13. PRESS: Compare every headline value with a temporary validation table and SQL query under the same filters.
14. PRESS: Ctrl+S and save the Power BI project/file to its documented local location.
15. LOOK FOR: Capture a screenshot only after values and interactions are verified; redact sensitive connection details.
16. DO NOT CONTINUE UNTIL: Page layout, values, filters, interactions, tooltips/drill-through, and accessibility checks pass.

### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

3	Primary chart	page-specific date/category axis	explicit measure	title, labels, sort	test each slicer	[ENTER]
4	Secondary comparison	appropriate dimension	explicit measure	avoid misleading axis	test cross-highlight	[ENTER]

Visual order	Visual type	Field placement	Aggregation/ measure	Formatting	Interaction check	My verified result
5	Detail table/matrix	keys hidden; readable attributes	measures	totals/subtotals deliberate	drill/tooltip check	[ENTER]
6	Slicers	date and relevant dimensions	no implicit aggregation	dropdown/list/range	inspect every visual	[ENTER]

### Screenshot checkpoint

- **Application:** Power BI Desktop.
- **Window:** Report view with Data Quality selected and the Filters pane showing no accidental hidden filter.
- **Include:** Page title, all visuals, current slicer state, and one visible validation element if readable.
- **Hide:** Server names beyond local examples, Windows username when unnecessary, account email, tokens, passwords, and unrelated desktop content.
- **Crop out:** Other applications and empty desktop area.
- **Recommended filename:** docs/images/phase17\_09\_data-quality-verified.png.
- **README placement:** Dashboard/report-pages section after the architecture and validation sections.
- **What it proves:** The verified page existed with the shown filter state; it does not prove every other filter combination.

### Interview-ready explanation

"I built the Data Quality page from governed measures, set interactions deliberately, avoided grain/denominator traps, and reconciled displayed values to SQL under matching filters before using the screenshot as portfolio evidence."

## What your screen should look like now

- The new Phase 17 objects are visible in their owning application.
- The current branch remains the intended feature branch.
- The current database, catalog, schema, Power BI model, or GitHub run is still identifiable.
- Verification output is visible or recorded; no object is marked complete solely because creation code was displayed.
- Any failed toy demonstration has been repaired or isolated.

## Lesson 17.4 completion checklist

☐

Every required object was built separately — [STATUS]

☐

Every object has a declared responsibility/grain — [STATUS]

☐

Inputs and outputs were inspected — [STATUS]

☐

A rerun or alternate-result branch was tested where applicable — [STATUS]

☐

Counts, keys, measures, relationships, or settings were independently validated — [STATUS]

☐

I can explain one failure and its safest recovery — [STATUS]

## Safe stopping point

Stop only after the active command, database transaction, Databricks cell/Job, Python process, warehouse load, or Power BI refresh finishes. Save all files and the Power BI project. Record uncommitted Git changes and exact resume action. Resume at [Lesson 17.5](#).

## Lesson 17.5 — Verify, troubleshoot, commit, teach back, and stop safely

### What your screen should look like before starting

The Phase 17 outputs are visible, all runs are finished, open files are saved, and you can state the active branch and execution context. Any error you encountered has a recorded message and has not been hidden by deleting evidence.

## Design decision — Verification before automation

---

### Question:

Should the phase prioritize a visible manual verification or jump directly to automation?

### Options considered:

- Manual verification first, then automation.
- Automation without a known-good baseline.
- Manual operation forever.

### Beginner path selected:

Establish one verified manual baseline and then automate repeatable checks.

### Why this path was selected:

A known-good example makes failures interpretable and prevents automation from hiding a wrong assumption.

### Tradeoff:

The first run takes longer.

### What a company might do instead:

Teams often pair infrastructure as code and automated tests with controlled bootstrap and acceptance procedures.

### How to explain this in an interview:

I established a verified baseline, then encoded the same contract in tests and orchestration so automation preserved meaning rather than just speed.

## If you see Result A

---

Each page answers its audience question and visible values match the validated semantic model. Record the exact result, perform the named independent verification, and continue only when the gate is satisfied.

## If you see Result B

---

A visual is blank, misleading, differently filtered, over-aggregated, or inconsistent with SQL/DAX validation. Treat this as information, not permission to delete or overwrite. Follow the branch-specific diagnostic in the current action, preserve evidence, and continue only after the state is understood.

## If you see an error

---

Read the first meaningful error line, redact secrets, and verify the application, path, branch, server/database, catalog/schema, batch ID, parameters, version/tier, and object name. Run the smallest observational check first. Do not reset Git history, drop data, disable a rule, force-push, or replace the target merely to make the error disappear.

## Phase-specific verification gate

---

☐

Required files/objects exist in the exact location.

☐

I personally created or configured them.

☐

I ran the phase commands in the documented context.

☐

I inspected the output rather than relying on a green icon alone.

☐

Counts, keys, relationships, measures, checksums, statuses, or settings meet the declared contract.

☐

Same-batch/rerun behavior is known where applicable.

☐

A controlled failure or realistic alternate-result branch was tested safely where applicable.

☐

No password, token, or secret appears in tracked files, screenshots, notebook output, terminal history pasted into documentation, or staged changes.

Actual verified result: [ENTER VERIFIED RESULT].

## Point-of-failure troubleshooting record

---

### Exact or representative error message:

[PASTE THE FIRST MEANINGFUL ERROR, WITH SECRETS REDACTED]

### What it means in plain language:

[WRITE YOUR INTERPRETATION]

### Most likely cause:

[WRITE ONE TESTABLE HYPOTHESIS]

### What not to do:

Do not delete data, drop databases, reset Git history, force-push, disable constraints, edit raw evidence, change a quality threshold, or expose credentials merely to make the symptom disappear.

### First diagnostic action:

[ENTER THE SMALLEST OBSERVATIONAL CHECK]

### How to read the diagnostic result:

[RESULT A MEANS... / RESULT B MEANS...]

### Safest fix:

[ENTER THE NARROW FIX]

### Alternative fix when applicable:

[ENTER OR N/A]

### How to verify the fix:

[ENTER THE INDEPENDENT RECHECK]

### How to return to the main tutorial:

Resume at the exact action number that failed; do not skip its verification gate.

## Screenshot checkpoint

---

**Application(s) that should be visible:** Power BI Desktop Report view, Format pane, Selection pane, and SSMS validation windows.

**Window/panel:** Show each verified report page under a documented slicer state.

**Sensitive information to hide:** Passwords, tokens, connection strings, email addresses, cloud account IDs, unnecessary Windows profile details, and any secret revealed by an error.

**Include:** The object name, batch/run ID when relevant, result/status, and enough surrounding UI to prove which application and layer is shown.

**Crop out:** Unrelated desktop windows, notification previews, bookmarks, chat, and empty background.

**Recommended filename:** docs/images/phase17\_build-and-validate-all-power-bi-report-pages\_verified.png.

**Recommended repository folder:** docs/images/.

**README placement:** The section describing Phase 17's verified result; do not use the image before the result is actually verified.

**What it proves:** The visible state existed under the shown context. It does not prove hidden rows, other batches, every filter combination, or a later run.

[ADD YOUR VERIFIED SCREENSHOT HERE]

## Git checkpoint after the verified Phase 17 changes

---

Do not use `git add .` until you understand that it stages every matching change under the current directory, including files you did not intend. Prefer targeted staging after inspecting status and diffs.

### Save open work

1. PRESS: In VS Code, press Ctrl+K, then S if you use **Save All**, or press Ctrl+S in every modified editor.
2. In Power BI, press Ctrl+S and confirm the local file location.
3. Wait for database, Python, Databricks, and refresh operations to finish; Git does not capture uncommitted database/cloud state.

## Action 17.5.G1 — Verify the repository root before Git operations

---

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
git rev-parse --show-toplevel
```

### Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `git rev-parse --show-toplevel` — `git` calls the Git version-control program; `rev-parse` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-toplevel` is a command option or flag; its exact behavior is defined beside the command

### Does it change anything?

This is intended to inspect or validate state rather than change it.

### Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

## Action 17.5.G2 — Verify the active Git branch

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

VS Code integrated PowerShell terminal

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

#### Command or code (PowerShell):

```
git branch --show-current
```

#### Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

#### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

#### What each part means:

- **Line 1:** `git branch --show-current` — `git` calls the Git version-control program; `branch` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--show` is a command option or flag; its exact behavior is defined beside the command; `-current` is a command option or flag; its exact behavior is defined beside the command

#### Does it change anything?

This is intended to inspect or validate state rather than change it.

#### Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

#### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

#### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

#### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

#### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

#### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

## Action 17.5.G3 — Inspect all current Git changes

---

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
git status --short
```

### Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

### Does it change anything?

This is intended to inspect or validate state rather than change it.

### Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

**Interpret `git status --short`**

- `??` means untracked: Git sees a new path but it is not staged.
- `M` means modified in the working tree but not staged.
- `M` means the staged version differs from the last commit.
- `MM` means a staged version exists and the file has additional unstaged edits.
- `A` means staged as a new file.
- `D` means deletion; stop and investigate unless deletion is deliberate.
- `R` means rename; inspect both old and new paths.
- A blank result means the working tree is clean. It does not prove database, Databricks, or Power BI work occurred.

## Action 17.5.G4 — Inspect the unstaged diff for `powerbi/dashboard_requirements.md`

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

VS Code integrated PowerShell terminal

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
git diff -- "powerbi/dashboard_requirements.md"
```

### Where to enter it:

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `git diff -- "powerbi/dashboard_requirements.md"` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--` is a command option or flag; its exact behavior is defined beside the command; `"powerbi/dashboard_requirements.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

### Does it change anything?

This is intended to inspect or validate state rather than change it.

### Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

## Action 17.5.G5 — Stage only the reviewed file `powerbi/dashboard_requirements.md`

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

VS Code integrated PowerShell terminal

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project` and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (PowerShell):**

```
git add -- "powerbi/dashboard_requirements.md"
```

**Where to enter it:**

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `git add -- "powerbi/dashboard_requirements.md"` — `git` calls the Git version-control program; `add` moves selected changes into the staging area; `--` is a command option or flag; its exact behavior is defined beside the command; `"powerbi/dashboard_requirements.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

### Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

### What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

### How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

For every additional intended path, run a separate targeted `git add -- "path"` after its diff is reviewed. Never stage `.env`, generated raw batches, credentials, tokens, local database files, or an unverified Power BI artifact.

## Action 17.5.G6 — Inspect the staged diff

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (PowerShell):**

```
git diff --cached
```

**Where to enter it:**

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `git diff --cached` — `git` calls the Git version-control program; `diff` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `--cached` is a command option or flag; its exact behavior is defined beside the command

**Does it change anything?**

This is intended to inspect or validate state rather than change it.

**Is it safe to rerun?**

Normally safe to rerun because it is observational, but still confirm the execution location first.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

## Action 17.5.G7 — Create the Phase 17 commit

---

**Application:**

Power BI Desktop

**Window or panel:**

VS Code integrated PowerShell terminal

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Power BI Desktop** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (PowerShell):**

```
git commit -m "feat: build verified power bi report pages"
```

**Where to enter it:**

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `git commit -m "feat: build verified power bi report pages"` — `git` calls the Git version-control program; `commit` records the staged snapshot; `-m` asks Python to run an installed module; `"feat: build verified power bi report pages"` is a quoted literal; the quotation marks preserve spaces or mark text

**Does it change anything?**

This can change files, Git state, packages, database objects, or data.

**Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

## Action 17.5.G8 — Verify the new commit

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

VS Code integrated PowerShell terminal

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (PowerShell):**

```
git log -1 --oneline --decorate
```

**Where to enter it:**

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `git log -1 --oneline --decorate` — `git` calls the Git version-control program; `log` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-1` is a command option or flag; its exact behavior is defined beside the command; `--oneline` is a command option or flag; its exact behavior is defined beside the command; `--decorate` is a command option or flag; its exact behavior is defined beside the command

**Does it change anything?**

This is intended to inspect or validate state rather than change it.

**Is it safe to rerun?**

Normally safe to rerun because it is observational, but still confirm the execution location first.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use

git status and git branch --show-current; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

## Action 17.5.G9 — Push the feature branch and set upstream

---

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

VS Code integrated PowerShell terminal

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project and the open Power BI Desktop project/model view named in the action. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (PowerShell):**

```
git push -u origin "$(git branch --show-current)"
```

**Where to enter it:**

VS Code integrated PowerShell terminal. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `git push -u origin "$(git branch --show-current)"` — `git` calls the Git version-control program; `push` sends local commits to a remote repository; `-u` is a command option or flag; its exact behavior is defined beside the command; `origin` the conventional name of the GitHub remote; `"$(git branch --show-current)"` is a quoted literal; the quotation marks preserve spaces or mark text

**Does it change anything?**

This can change files, Git state, packages, database objects, or data.

**Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 17 lesson index](#)

**Verify on GitHub**

1. CLICK: Open the repository page in a browser.
2. CLICK: Open the branch selector above the file list.
3. TYPE THIS: The exact branch name returned locally.
4. CLICK: Select that branch.
5. LOOK FOR: The latest commit message `feat: build verified power bi report pages` and the intended changed paths.
6. CLICK: Open each changed file and confirm the GitHub version matches the staged diff.
7. Do not merge solely because the push succeeded; CI and review must pass.

## Push-rejected recovery

If Git says the remote contains work you do not have, do not use `--force`. Run `git fetch origin`, inspect `git log --oneline --graph --decorate --all -20`, then rebase or merge only after understanding the divergence. Resolve conflicts one file at a time, run tests again, and push normally. A rejection protects remote work; it is not permission to overwrite it.

## Explain it in your own words

---

Without copying the model answer, explain:

1. What you created or configured in Phase 17.
2. Why it exists.
3. Where it is located on your computer, in a database, in Databricks, in Power BI, or on GitHub.
4. What information enters it.
5. What information leaves it.
6. How it connects to the next phase.
7. How you verified it.
8. What could cause it to fail.
9. Which decision/tradeoff you could defend in an interview.

## My answer

[WRITE YOUR ANSWER BEFORE READING THE REFERENCE]

## OPTIONAL REFERENCE ANSWER — PHASE 17 TEACH-BACK MODEL

---

Read this only after completing **MY TASK** and using the three hints in order. The model is a learning reference, not evidence of your execution.

“Phase 17 created the verified boundary described by **Build and validate all Power BI report pages**. It consumes only the outputs accepted from earlier phases, produces a named and auditable handoff, and records enough metadata and tests to detect wrong context, missing data, duplicates, failed rules, or unsafe reruns. I verified the result in its owning application and connected the evidence to Git without claiming that displayed instructions were executed.”

## Mini quiz

---

1. Multiple choice: Why does Phase 17 occur at this point in the source-to-consumption chain? A) Because menu order is arbitrary. B) Because its verified upstream input now exists. C) Because later phases do not depend on it. D) To create portfolio screenshots before validation.
  2. True or false: A command that displays no error is automatically verified even when it ran in the wrong folder, database, catalog, schema, branch, or filter context.
  3. Fill in the blank: The statement that defines what one row represents is the table or entity \_\_\_\_\_.
  4. What command would you use first to confirm the PowerShell current folder before a repository command?
  5. Troubleshooting: Your output differs from the example. What should you check before deleting, overwriting, resetting, force-pushing, or weakening a test?
  6. Design choice: Explain one tradeoff of Track A and one production alternative.
  7. Code reading: Why are input, accepted, rejected, and deduplicated counts recorded separately?
  8. Ownership: Which status may you select only after personally performing and inspecting the verification?
- 

## Mini quiz answer key and explanations

---

1. **B.** This phase is ordered after its prerequisites so its output has a trustworthy input. A is wrong because order is intentional; C is wrong because later phases depend on the handoff; D is wrong because screenshots follow verification.
2. **False.** Lack of an error proves only that the application accepted something; context and independent verification still matter.
3. **Grain.** Grain is the precise meaning of one row. A key identifies a row, but it does not by itself state the row's business meaning.
4. **Get-Location.** It shows the shell's current folder. `git rev-parse --show-toplevel` separately verifies the repository root when inside a clone.

5. Check application, folder/path, branch, server/database, catalog/schema, batch ID, parameters, source/target grain, filter context, version/tier differences, and the first meaningful error. Destructive changes are not a diagnostic step.
6. Track A has manual upload/download boundaries and batch latency. A production alternative is routable private connectivity with cloud object storage/managed warehouse, identities, and automated orchestration.
7. Separate counts make every row outcome explainable. A single final count can hide silent drops, duplicates, or records that moved to quarantine.
8. **Verified by me / VERIFIED BY USER.** PLANNED, CREATED BY USER, and RUN BY USER describe earlier states; only inspected evidence supports verification.

## What your screen should look like now

---

- The phase output and final validation are saved or visible.
- The intended feature branch is still active.
- `git status` is either clean after the commit or lists only deliberately deferred work recorded in the journal.
- The branch exists on GitHub after a successful push.
- No database transaction, Databricks run, loader, test process, or Power BI refresh is still active.
- The next phase's required input is identifiable.

## Lesson 17.5 completion checklist

---

☐

I completed the verification gate with my actual results — [STATUS]

☐

I recorded at least one realistic failure, alternate result, or diagnostic path — [STATUS]

☐

I captured and redacted the required screenshot only after verification — [STATUS]

☐

I reviewed, staged, committed, pushed, and verified only the intended Git changes — [STATUS]

☐

I completed the teach-back, quiz, answer review, and learning journal — [STATUS]

☐

I can name the exact verified handoff to the next phase — [STATUS]

## Safe stopping point

---

All files must be saved. The terminal may be closed after the Git result is recorded. SSMS/pgAdmin may be closed after queries finish and transactions are committed/rolled back. Databricks compute may be stopped when no Job or notebook is running. Power BI may be closed after saving. Resume from the next phase's screen-start checklist and re-verify root, branch, connection, and latest accepted batch.

## How this phase connects to the next phase

---

Phase 18 reviews every location where secrets, compute cost, or sensitive data can appear.

## Phase 17 completion checklist

---

☐

Phase goal explained in my own words — [STATUS]

☐

Required files/objects created by me — [STATUS]

☐

Commands run by me — [STATUS]

☐

Output independently inspected — [STATUS]

☐

Failure/alternate branch understood — [STATUS]

☐

Screenshot captured and redacted — [STATUS]

☐

Targeted Git commit exists — [STATUS]

☐

Branch pushed and verified on GitHub — [STATUS]

☐

Quiz completed before answer key — [STATUS]

☐

Journal completed — [STATUS]

☐

Final phase status manually set — [ ] Not started / [-] In progress / [x] Verified by me / [!] Needs troubleshooting

[Back to the master table of contents](#)

# Phase 18 — Secure secrets, control cost, and review operational settings

[Back to the master table of contents](#)

**Track:** Track A required

**Status when first opened:** PLANNED

**Completion rule:** The phase is not complete because its instructions exist. Mark it VERIFIED BY USER only after you perform the work, inspect the output, and save evidence.

## Why this phase happens now

---

**Earlier work this phase depends on:** A repository with secrets excluded and cost-sensitive settings recorded.

**What would go wrong if it happened earlier:** You would create objects without a verified requirement, valid upstream input, protected repository state, or known execution environment.

**Later work that depends on it:** Phase 19 automates local, infrastructure-free quality checks on every change.

**Decision being made:** Choose and verify the simplest local-first method that teaches the professional concept without

pretending that local services are publicly reachable.

**Alternatives:** A company could use managed cloud databases, infrastructure as code, service principals, direct JDBC publication, deployment bundles, or streaming. Those options are discussed as tradeoffs, not substituted silently.

**Beginner path selected:** Track A: local SQL Server and PostgreSQL, Python batch extracts, manual governed upload to Databricks, Delta Bronze/Silver/Gold, manual verified export, local SQL Server warehouse, and Power BI Import.

**Reason for the order:** Requirements become source decisions; sources become generated data; source data becomes extraction batches; batches become Bronze; Bronze becomes Silver; Silver becomes Gold; Gold becomes warehouse and Power BI input.

## Phase 18 lesson index

---

1. [Lesson 18.1 — Understand the phase and starting screen](#)
2. [Lesson 18.2 — Perform the notebook-guided actions one at a time](#)
3. [Lesson 18.3 — Create and understand the phase files](#)
4. [Lesson 18.4 — Build and validate required objects](#)
5. [Lesson 18.5 — Verify, troubleshoot, commit, teach back, and stop safely](#)

## Lesson 18.1 — Understand the phase and starting screen

---

### What your screen should look like before starting

---

- **Application open:** VS Code, PowerShell, Git, GitHub, Databricks settings, and Power BI options.
- **Window in front:** The application named by the first action; do not keep an installer, database editor, notebook, and Power BI dialog stacked ambiguously.
- **Repository folder:** C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project when repository work is required. Verify User on your computer.
- **Git branch:** A feature branch, not a detached commit. Run `git branch --show-current` and record the exact result.
- **Database/workspace connection:** The connection named in the action, not merely the most recent connection.
- **Files that should already exist:** Only files from verified earlier phases. Do not pre-create the full tree.
- **Files that should not exist yet:** New Phase 18 files remain absent until their creation lesson.
- **Terminal prompt:** It should end in the expected repository path or another explicitly named folder.
- **Previous verification:** Phase 17 must be verified when this phase has a prerequisite.

## Three-level explanation of the phase

---

### Level 1 — Child-simple explanation

Imagine building a store from labeled boxes. This phase handles one box, checks that the label is correct, and makes sure the next box receives the right thing. You do not pour all boxes together and hope the result is understandable.

### Level 2 — Northstar Retail project explanation

Phase 18 creates the specific Northstar Retail files, database objects, transformations, tests, model objects, or evidence described in the lessons. Every output keeps a visible connection to its source and batch so you can trace an order, customer, product, campaign, return, shipment, or inventory record.

### Level 3 — Professional explanation

This phase establishes a controlled boundary in an end-to-end batch platform. It defines contracts, execution context, idempotency behavior, quality expectations, evidence, and handoff artifacts so the downstream layer can be reproduced and reviewed independently.

## Applications to open

---

VS Code, PowerShell, Git, GitHub, Databricks settings, and Power BI options. Open only the application needed for the immediate action. Extra windows increase the chance of typing a command into the wrong context.

## Phase status gate

---

I changed this phase from [ ] Not started to [-] In progress in the master tracker.

☐

I verified the repository root when repository work is required.

☐

I verified the current branch.

☐

I identified the exact server/database, Databricks workspace/catalog/schema, or Power BI file.

☐

I read the phase ordering explanation.

## What your screen should look like now

---

- The Phase 18 lesson index, starting-screen checklist, and three explanation levels remain visible in this workbook.
- Only the applications required for the next lesson are open; no installer, database transaction, notebook run, or Power BI refresh was started merely to read orientation material.
- The intended repository path, active branch, server/database, Databricks workspace, or Power BI file has been written down when it applies.
- No new Phase 18 project file or object has been created yet unless the lesson explicitly instructed you to create it.
- The Phase 18 master-tracker row is marked [-] In progress only after you personally updated it.

## Lesson 18.1 completion checklist

---

☐

I read why Phase 18 happens now — [STATUS]

☐

I can give the child-simple, Northstar-specific, and professional explanations — [STATUS]

☐

I identified the exact applications and execution context required next — [STATUS]

☐

I verified prerequisites instead of assuming they are complete — [STATUS]

☐

I updated the progress tracker myself — [STATUS]

## Safe stopping point

---

No command, database transaction, Databricks run, loader, or Power BI refresh should be active after this orientation lesson. Save any journal note you created. You may close the workbook viewer and applications. When returning, reopen [Lesson 18.2](#), re-read its starting-screen checklist, and verify the repository root, branch, connection, and workspace before performing an action.

[Back to the Phase 18 lesson index](#)

## Lesson 18.2 — Perform the notebook-guided actions one at a time

---

### What your screen should look like before starting

---

The Phase 18 start gate is checked, only the needed application is in front, and the current context has been verified. The following retained lesson material preserves the Northstar terminology and exercise framing; the action cards then turn each hands-on step into a written screen-recording sequence.

### Retained phase lesson, exercises, rules, and expected results

---

**Track:** Track A required

**Ownership status at start:** Workbook instructions exist; your execution is not yet verified.

**Evidence rule:** Replace placeholders only after the verification steps pass.

## 1. What you are building

A no-secrets configuration pattern, .gitignore, .env.example, Databricks secret guidance, least-privilege SQL roles, read-only analyst access, development/production separation, log-redaction rules, synthetic-data classification, secret-scanning checklist, and cost shutdown checklist.

## 2. Why it matters

A portfolio project can still leak real passwords, tokens, machine details, or cloud spend. Security and cost controls are design requirements, not cleanup after the pipeline works.

## 3. Words to know

Term	Plain-language definition
Secret	A password, token, private key, connection string, or credential that grants access.
Environment variable	A process-level name/value used to supply configuration without writing a secret into code.
.env file	A local text file commonly used for environment variables; it must be ignored by Git.
Least privilege	Grant only the minimum access needed for a task.
Read-only role	A database permission group that can query approved objects but cannot change them.
Secret scope	A Databricks-managed namespace for secret values, subject to workspace capabilities and permissions.
PII	Personally identifiable information; synthetic names/emails should still be handled as if their shape were sensitive.
Redaction	Removing or masking sensitive content from logs, screenshots, and error messages.
Configuration environment	A named set of settings such as development or production.
Compute auto-termination	Stopping idle cloud compute automatically to reduce cost.
Secret scanning	Searching repository content for credential-like patterns before commit/push.

## 4. What must already be completed

Local source/warehouse connections work through environment variables, the repository has no real credentials, and you can identify every service/database account used by the project.

## 5. Applications to open

Application	How to open it	Why it is open
VS Code	Open .gitignore, .env.example, config files, and security guide.	Review what is safe to publish.
Windows PowerShell	Open in repository root.	Create local .env, inspect tracked files, and run scans.
SSMS and pgAdmin	Connect with an administrative learning account only while creating read roles.	Grant and test minimum database permissions.
Databricks workspace settings/secret interface	Open only if available on your workspace tier.	Store cloud-connected credentials without notebooks or Git.
GitHub repository Settings/Security	Open the repository in a browser.	Review visibility, Actions, and secret alerts if available.

## 6. Exact click-by-click steps

**Beginner rhythm:** Read the whole step. Confirm the application and location. Perform only that step. Verify the visible result. Record an error before attempting a fix.

## 7. Exact commands, one code block at a time

## 8. Where each command runs

Never infer the execution location from the code language. The command headings above identify the application and folder/database/catalog. Before every PowerShell command, run `Get-Location`; before SQL, verify the selected database; before Spark, print the catalog/schema/batch widgets.

## TEACHING EXAMPLE

The following small example or reference pattern explains the concept before you attempt Northstar-specific work. Read it, then complete **MY TASK** without copying the answer.

### Line-by-line code explanation

Line or action	Meaning	Why it belongs here
Copy-Item .env.example .env	Creates a local ignored configuration file and opens it for editing.	Scripts need connection settings, but real values must not be placed in tracked templates.
git check-ignore -v .env	Shows why .env is ignored and whether any sensitive file is staged/untracked.	Assuming an ignore rule works is not sufficient.
python -m scripts.validation.scan_secrets	Scans text files for several common credential patterns.	It catches obvious mistakes before GitHub receives them.
IF DATA-BASE_PRINCIPAL_ID(N'northstar_analyst_reader') IS NULL	Creates a reusable read-only semantic-schema role without embedding credentials.	Power BI/analysts should not need table-write or database-owner permission.
-- TODO(USER): create/login names and passwords outside Git.	Creates a group role with read access to current and future digital tables.	The extraction account does not require object ownership or write privileges.

### Local-first security boundary

Databricks does not receive local SQL Server/PostgreSQL passwords in Track A. Python runs on your Windows machine, extracts to files, and you manually upload a batch. This is less automated but avoids pretending a cloud workspace can safely reach localhost.

### Cost truthfulness

Free or trial labels, quotas, and availability can change. Use the official source register near the beginning of this workbook, read the current account page before starting compute, record what you actually used, enable auto-stop where available, and never claim “zero cost” unless your own billing confirms it.

## MY TASK

Prove that secrets are excluded from Git, create/test read-only database roles in a safe local environment, document the Track A credential boundary, review logs/screenshots, and complete the security and cost checklists.

## STARTER SKELETON

```
SECRET/RESOURCE: TODO(USER)
OWNER: TODO(USER)
USED BY: TODO(USER)
STORAGE LOCATION: environment variable / secret manager / identity
MINIMUM PERMISSIONS: TODO(USER)
ROTATION/REVOCACTION METHOD: TODO(USER)
LOG REDACTION TEST: TODO(USER)
COST CONTROL: TODO(USER)
EVIDENCE: TODO(USER)
```

**Acceptance criteria:** No real credential or private key is tracked; .env ignore behavior is proven; source extraction and analyst access use least privilege; log/screenshots are reviewed; cloud/local cost shutdown steps are recorded; an accidental-secret response procedure is understood.

## HINT 1 — CONCEPT

Treat every value that grants access as a secret even when the data is synthetic.

## HINT 2 — PSEUDOCODE

For each component list identity, minimum actions, storage method, test for denied write, and shutdown/rotation path.

## HINT 3 — NEAR-COMPLETE PATTERN

Use `.env.example` for variable names only, local `.env` for values, database group roles for permissions, and a pre-push scan plus manual staged-diff review.

### 13. Expected files or output

- Verified ignored `.env` file.
- Passing secret-pattern scan and reviewed staged diff.
- Read-only SQL Server and PostgreSQL role test evidence.
- Completed secret inventory and classification notes.
- Cost/shutdown checklist with actual services used.
- Sanitized logs and screenshot review.

### 14. How to verify

- `git ls-files` contains no `.env` or credential file.
- Read-only users can SELECT required objects and cannot modify them.
- Track A Databricks notebooks contain no local database connection string.
- Logs do not print complete connection URLs/passwords/tokens.
- Generated sample data is explicitly labeled synthetic.
- Cloud compute/warehouse auto-stop or manual shutdown is recorded.
- Secret rotation steps are known before any public push.

### 15. Automated tests

- Ignore-rule test with `git check-ignore`.
- Secret scanner plus manual staged-diff review.
- Positive SELECT and negative INSERT permission tests.
- Log redaction inspection.
- Repository history spot check before publication.
- Cloud billing/resource inventory check.

### 16. Common errors and exact fixes

Message/symptom	Likely cause	Exact diagnostic	Safe fix	Verify
<code>.env</code> appears in git status	Ignore rule is missing, malformed, or the file was already tracked.	<code>git check-ignore -v .env</code> and <code>git ls-files .env</code> .	Add rule; if already tracked, use <code>git rm --cached .env</code> , rotate any exposed credential, then commit the removal.	<code>.env</code> is ignored/untracked and credential is rotated if needed.
Permission denied for SELECT	Role/user mapping, schema USAGE, or object SELECT grant is missing.	Inspect current user and database role membership.	Grant only the missing read permission; do not make the user owner/db_owner.	SELECT succeeds; write still fails.
Read-only account can modify data	It inherited a broader role or direct grant.	Inspect role memberships and effective grants.	Revoke broad membership/grants, reconnect, retest.	INSERT/UPDATE/DELETE are denied.
Secret scanner reports a template	Example resembles a real token/password pattern.	Open the exact file/line and determine whether it is a real secret.	Rotate if real; replace with unmistakable placeholder if fake; document false positive only when justified.	Scan passes and no usable credential exists.
Unexpected cloud charge/quota failure	Compute/storage remained active or free-tier quota was exceeded.	Open provider billing/quota and resource/run history.	Stop/delete unused resources, reduce scale/schedule, and document cost guardrails before retry.	No unintended active resource and next run fits budget/quota.

For deeper tool-specific diagnosis, use [the troubleshooting index](#) near the end of [this workbook](#).

## 17. Explain it in your own words

---

1. Why is `.env.example` safe while `.env` is not?
2. Why does a Power BI reader not need warehouse write access?
3. Why are synthetic names still classified as PII-like?
4. What must happen after a real secret is committed?

Write your answers in [the learning-journal fields in this phase](the learning-journal fields in this phase). Do not copy the wording above.

## 18. Mini quiz

---

1. Which command proves the ignore rule that applies to `.env`?
2. Does deleting a committed secret from the latest file make it safe again?
3. Why does Track A not place local database credentials in Databricks?

Record your answers before opening the answer key.

## 19. Screenshot checkpoint

---

Capture passing scans, ignore proof, role membership and denied-write tests, plus compute auto-stop/resource shutdown settings. Redact usernames, server endpoints, tokens, and billing identifiers.

Save the image under `docs/images/` with a descriptive filename. Check that no credential, token, password, or unnecessary personal account detail is visible.

## 20. Git checkpoint and suggested commit message

---

Run `git status`, review the Source Control diff in VS Code, stage only the intended files, then commit:

```
security: add least privilege secret and cost controls
```

Push the feature branch only after tests pass.

## 21. Completion checklist

---

Use one status per item: Not started, In progress, Verified by me, or Needs troubleshooting.

☐

`.env` ignore behavior proven — [STATUS]

☐

No secrets tracked or staged — [STATUS]

☐

SQL Server read role tested — [STATUS]

☐

PostgreSQL read role tested — [STATUS]

☐

Databricks credential boundary documented — [STATUS]

☐

Logs/screenshots sanitized — [STATUS]

☐

Synthetic classification documented — [STATUS]

☐

Cost shutdown controls verified — [STATUS]

Attempt the task and record what failed before reading the optional reference answer in this phase: [the optional reference-answer section later in this workbook#phase-18](the optional reference-answer section later in this workbook#phase-18). The quiz answer is in [the answer-key section immediately after the quiz in this workbook#phase-18](the answer-key section immediately after the quiz in this workbook#phase-18).

---

**Next phase:** Phase 19 automates the repository checks through GitHub Actions and a safe branch/pull-request workflow.

## Required action cards

---

### Action 18.2.1 — Open .gitignore and confirm .env, .venv, logs, run artifacts, generated raw data, PBIX working files, an

---

**Application:**

Visual Studio Code

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Open .gitignore and confirm .env, .venv, logs, run artifacts, generated raw data, PBIX working files, an. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Open .gitignore and confirm .env, .venv, logs, run artifacts, generated raw data, PBIX working files, and local connection files are excluded as intended.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:**

#### Step 1

**Action**

Open .gitignore and confirm .env, .venv, logs, run artifacts, generated raw data, PBIX working files, and local connection files are excluded as intended.

**Before continuing**☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

**What should happen:**

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**Expected example:**

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**What may look different:**

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**How to verify success:**

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**Do not continue unless:**

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 18 lesson index](#)

## Action 18.2.2 — Copy .env.example to .env in the repository root. Fill only local values in .env; never edit .env.examp

**Application:**

Visual Studio Code

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Copy .env.example to .env in the repository root. Fill only local values in .env; never edit .env.examp. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Copy .env.example to .env in the repository root. Fill only local values in .env; never edit .env.example to contain a real password.
4. Pause while the application finishes the operation; do not click the same control twice.

5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:****Step 2****Action**

Copy `.env.example` to `.env` in the repository root. Fill only local values in `.env`; never edit `.env.example` to contain a real password.

**Before continuing**☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

**What should happen:**

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**Expected example:**

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**What may look different:**

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**How to verify success:**

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**Do not continue unless:**

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Action 18.2.3 — Run `git check-ignore -v .env` and `git status --short`. Stop if `.env` appears as an untracked/staged file

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

### Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

### Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run `git check-ignore -v .env` and `git status --short`. Stop if `.env` appears as an untracked/staged file. This is one bounded construction or inspection task.

### Why this action comes now:

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

### Exact physical actions:

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Run `git check-ignore -v .env` and `git status --short`. Stop if `.env` appears as an untracked/staged file rather than ignored.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

### Command or code:

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

### Where to enter it:

Windows PowerShell or the VS Code PowerShell terminal. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

### What each part means:

## Step 3

### Action

Run `git check-ignore -v .env` and `git status --short`. Stop if `.env` appears as an untracked/staged file rather than ignored.

### Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**What may look different:**

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**How to verify success:**

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**Do not continue unless:**

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Action 18.2.4 — Review every script for `os.getenv/configuration` helpers and confirm errors identify missing variable names w

**Application:**

Visual Studio Code

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Review every script for `os.getenv/configuration` helpers and confirm errors identify missing variable names w. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Review every script for `os.getenv/configuration` helpers and confirm errors identify missing variable names without printing their values.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:****Step 4****Action**

Review every script for `os.getenv/configuration` helpers and confirm errors identify missing variable names without printing their values.

**Before continuing**☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

**What should happen:**

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**Expected example:**

**What you are about to do:**

Classify synthetic customer fields in the data dictionary. Use labels such as Synthetic PII-like so future rea. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Classify synthetic customer fields in the data dictionary. Use labels such as Synthetic PII-like so future real-data handling expectations are visible.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:**

## Step 10

### Action

Classify synthetic customer fields in the data dictionary. Use labels such as Synthetic PII-like so future real-data handling expectations are visible.

### Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Action 18.2.11 — Set development configuration names, catalogs, schemas, and sample volume separately from any optional product

### Application:

Visual Studio Code

### Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Set development configuration names, catalogs, schemas, and sample volume separately from any optional product. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Set development configuration names, catalogs, schemas, and sample volume separately from any optional production environment. Never reuse a production credential in a portfolio repository.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:****Step 11****Action**

Set development configuration names, catalogs, schemas, and sample volume separately from any optional production environment. Never reuse a production credential in a portfolio repository.

**Before continuing**☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

**What should happen:**

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**Expected example:**

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**What may look different:**

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**How to verify success:**

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**Do not continue unless:**

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Action 18.2.12 — Record compute choices and shutdown controls: local services, Databricks serverless/job quotas, SQL warehouse

---

**Application:**

Power BI Desktop

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Record compute choices and shutdown controls: local services, Databricks serverless/job quotas, SQL warehouse . This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Record compute choices and shutdown controls: local services, Databricks serverless/job quotas, SQL warehouse auto-stop, cloud database tiers, storage, egress, and Power BI licensing. Stop or delete unused cloud resources.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Power BI Desktop. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:**

## Step 12

### Action

Record compute choices and shutdown controls: local services, Databricks serverless/job quotas, SQL warehouse auto-stop, cloud database tiers, storage, egress, and Power BI licensing. Stop or delete unused cloud resources.

### Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Action 18.2.13 — Before every push, run the secret scan, inspect staged diff, and use the secret-scanning checklist in `docs/se

### Application:

Visual Studio Code

### Window or panel:

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

### Starting condition:

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Before every push, run the secret scan, inspect staged diff, and use the secret-scanning checklist in `docs/se`. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: Before every push, run the secret scan, inspect staged diff, and use the secret-scanning checklist in docs/security\_and\_cost.md.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:****Step 13****Action**

Before every push, run the secret scan, inspect staged diff, and use the secret-scanning checklist in docs/security\_and\_cost.md.

**Before continuing**☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

**What should happen:**

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

**Expected example:**

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

**What may look different:**

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

**How to verify success:**

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

**Do not continue unless:**

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

**Common mistake:**

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

**Exact recovery:**

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

**What you just accomplished:**

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

**How this connects to the project:**

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

## Action 18.2.14 — If a secret was ever committed, remove/rotate it immediately; deleting one file or commit is not enough because

---

**Application:**

Visual Studio Code

**Window or panel:**

Use the foreground window, sidebar, tab, dialog, query editor, terminal, notebook, or Power BI pane named in the action text. Close no unrelated window merely to make the screen match an example.

**Starting condition:**

The previous verification gate has passed. Any file you edited is saved. The correct branch, database connection, Databricks workspace, or Power BI file is still active.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

If a secret was ever committed, remove/rotate it immediately; deleting one file or commit is not enough because. This is one bounded construction or inspection task.

**Why this action comes now:**

It creates or verifies the exact input required by the next action; doing it later would make errors harder to localize.

**Exact physical actions:**

1. Bring the application named above to the front and confirm that no unrelated window has focus.
2. Read the starting condition and compare it with what is visible on your screen.
3. Perform only this immediate task: If a secret was ever committed, remove/rotate it immediately; deleting one file or commit is not enough because the credential may already be copied or remain in history.
4. Pause while the application finishes the operation; do not click the same control twice.
5. Inspect the visible result before changing another file, object, or setting.
6. Record the actual result in the verification field for this action.

**Command or code:**

No command is required in this action. Use only the clicks, keystrokes, observations, or writing task below.

**Where to enter it:**

Visual Studio Code. When the action is click-only, do not invent a command. When code is shown, use the named editor rather than a visually similar field.

**What each part means:**

### Step 14

**Action**

If a secret was ever committed, remove/rotate it immediately; deleting one file or commit is not enough because the credential may already be copied or remain in history.

### Before continuing

☐

I used the application named in this phase.

☐

I confirmed the current folder/database/catalog/schema.

☐

I can describe what changed on the screen or filesystem.

☐

I know which later verification proves this step worked.

### What should happen:

A visible file, folder, branch, connection, table, notebook, task, relationship, measure, visual, or verification result should appear exactly where the action predicts.

### Expected example:

Your exact values may differ. The expected result is the same *type* of object and the same required status, not necessarily the same timestamps, row counts, colors, generated IDs, or screen dimensions.

### What may look different:

Menu wording can vary by product release or account tier. Use the official-source register and look for the described object rather than guessing from an old screenshot.

### How to verify success:

Reopen or refresh the relevant panel, locate the named object, and inspect the property or output that proves it exists and is in the intended location.

### Do not continue unless:

You can point to the visible result and explain what it proves. Mark the action VERIFIED BY USER only after that check.

### Common mistake:

Combining several clicks or decisions, choosing a similarly named object, or continuing because no error dialog appeared.

### Exact recovery:

Stop at the current screen. Save a screenshot of the error if useful, hide sensitive values, and compare the selected location with the starting condition. Use Back or Cancel rather than Delete or Overwrite. Correct one mismatch and repeat only this action.

### What you just accomplished:

You completed one observable piece of the Northstar Retail platform and established a checkpoint that can be audited later.

### How this connects to the project:

The resulting object, decision, or evidence becomes an input to the next stage in the source-to-consumption chain.

[Back to the Phase 18 lesson index](#)

## Action 18.2.C1 — Windows PowerShell

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

Windows PowerShell

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (Powershell):

```
Copy-Item .env.example .env
```

### Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** Copy-Item .env.example .env — Copy-Item copies a selected file or folder; . is a path, relative location, branch-style name, or file argument; verify every character before running it; env.example is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; . is a path, relative location, branch-style name, or file argument; verify every character before running it; env is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use Get-Location or Test-Path; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

## Action 18.2.C2 — Windows PowerShell

---

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

Windows PowerShell

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Run one explained Powershell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (Powershell):**

```
notepad .env
```

**Where to enter it:**

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `notepad .env` — `notepad` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `env` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This is intended to inspect or validate state rather than change it.

### Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

## Action 18.2.C3 — Windows PowerShell

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

Windows PowerShell

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained Powershell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (Powershell):

```
git check-ignore -v .env
```

### Where to enter it:

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `git check-ignore -v .env` — `git` calls the Git version-control program; `check-ignore` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-v` is a command option or flag; its exact behavior is defined beside the command; `.` is a path, relative location, branch-style name, or file argument; verify every character before running it; `env` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This is intended to inspect or validate state rather than change it.

### Is it safe to rerun?

Normally safe to rerun because it is observational, but still confirm the execution location first.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

**Common mistake:**

**Command or code (Powershell):**

```
git status --short
```

**Where to enter it:**

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `git status --short` — `git` calls the Git version-control program; `status` shows tracked, staged, modified, and untracked work; `--short` is a command option or flag; its exact behavior is defined beside the command

**Does it change anything?**

This is intended to inspect or validate state rather than change it.

**Is it safe to rerun?**

Normally safe to rerun because it is observational, but still confirm the execution location first.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

## Action 18.2.C5 — Windows PowerShell

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

Windows PowerShell

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Run one explained Powershell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (Powershell):**

```
python -m scripts.validation.scan_secrets
```

**Where to enter it:**

Windows PowerShell. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `python -m scripts.validation.scan_secrets` — `python` invokes Python when that command name is registered; `-m` asks Python to run an installed module; `scripts.validation.scan_secrets` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

**Does it change anything?**

This is intended to inspect or validate state rather than change it.

**Is it safe to rerun?**

Normally safe to rerun because it is observational, but still confirm the execution location first.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

## Action 18.2.C6 — SSMS query window (SQL Server / T-SQL)

**Application:**

SQL Server Management Studio (SSMS)

**Window or panel:**

SSMS query window (SQL Server / T-SQL)

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Run one explained Sql instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **SQL Server Management Studio (SSMS)** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (Sql):**

```
IF DATABASE_PRINCIPAL_ID(N'northstar_analyst_reader') IS NULL
CREATE ROLE northstar_analyst_reader;
GRANT SELECT ON SCHEMA::semantic TO northstar_analyst_reader;
-- TODO(USER): CREATE USER [your_local_read_login] FOR LOGIN [your_local_read_login];
-- TODO(USER): ALTER ROLE northstar_analyst_reader ADD MEMBER [your_local_read_login];
```

**Where to enter it:**

SSMS query window (SQL Server / T-SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `IF DATABASE_PRINCIPAL_ID(N'northstar_analyst_reader') IS NULL` — `IF` begins a conditional decision; `DATABASE_PRINCIPAL_ID` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `(` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `N` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `'northstar_analyst_reader'` is a quoted literal; the quotation marks preserve spaces or mark text; `)` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `IS` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NULL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 2:** `CREATE ROLE northstar_analyst_reader;` — `CREATE` defines a new database object; `ROLE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_analyst_reader` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `GRANT SELECT ON SCHEMA::semantic TO northstar_analyst_reader;` — `GRANT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SELECT` requests data without changing it unless combined with a modifying statement; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SCHEMA` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `::` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `semantic` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_analyst_reader` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `-- TODO(USER): CREATE USER [your_local_read_login] FOR LOGIN [your_local_read_login];` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 5:** `-- TODO(USER): ALTER ROLE northstar_analyst_reader ADD MEMBER [your_local_read_login];` is a comment for a human reader; it normally does not change data or execute business logic.

**Does it change anything?**

This can change files, Git state, packages, database objects, or data.

**Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

## Action 18.2.C7 — pgAdmin Query Tool or psql (PostgreSQL SQL)

---

**Application:**

pgAdmin 4 or PostgreSQL psql, as named in the action

**Window or panel:**

pgAdmin Query Tool or psql (PostgreSQL SQL)

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Run one explained Sql instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **pgAdmin 4 or PostgreSQL psql, as named in the action** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (Sql):**

```
-- TODO(USER): create/login names and passwords outside Git.
CREATE ROLE northstar_digital_reader NOLOGIN;
GRANT CONNECT ON DATABASE northstar_digital TO northstar_digital_reader;
GRANT USAGE ON SCHEMA digital TO northstar_digital_reader;
GRANT SELECT ON ALL TABLES IN SCHEMA digital TO northstar_digital_reader;
ALTER DEFAULT PRIVILEGES IN SCHEMA digital
GRANT SELECT ON TABLES TO northstar_digital_reader;
```

**Where to enter it:**

pgAdmin Query Tool or psql (PostgreSQL SQL). Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** `-- TODO(USER): create/login names and passwords outside Git.` is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** `CREATE ROLE northstar_digital_reader NOLOGIN;` — `CREATE` defines a new database object; `ROLE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_digital_reader` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `NOLOGIN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 3:** `GRANT CONNECT ON DATABASE northstar_digital TO northstar_digital_reader;` — `GRANT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `CONNECT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `DATABASE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_digital` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_digital_reader` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 4:** `GRANT USAGE ON SCHEMA digital TO northstar_digital_reader;` — `GRANT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `USAGE` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SCHEMA` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `digital` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_digital_reader` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation
- **Line 5:** `GRANT SELECT ON ALL TABLES IN SCHEMA digital TO northstar_digital_reader;` — `GRANT` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SELECT` requests data without changing it unless combined with a modifying statement; `ON` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `ALL` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TABLES` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `IN` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `SCHEMA` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `digital` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `TO` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `northstar_digital_reader` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

## What your screen should look like now

Each action you actually performed has a visible result and a recorded ownership status. You have not marked unrun reference commands as complete. The branch, connection, batch, and application context remain known.

## Lesson 18.2 completion checklist

☐

I performed actions in order — [STATUS]

☐

I verified each command location — [STATUS]

☐

I distinguished typed text from observed output — [STATUS]

☐

I recorded differences caused by versions/tier — [STATUS]

☐

I stopped at the first unexplained error — [STATUS]

## Safe stopping point

---

Save open work and record the next action number. Close an application only after its operation is complete. On return, re-open the Phase 18 starting-screen checklist and re-verify the active context.

## Lesson 18.3 — Create and understand the phase files

---

### What your screen should look like before starting

---

VS Code Explorer shows the repository root, the intended feature branch is active, and no Phase 18 file is assumed to exist merely because a reference answer appears below. Create each folder only when its first file is needed.

#### Folder introduction — docs/

**Exact folder name:** docs

**Exact parent:** repository root

**Why it is needed now:** Phase 18 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

**What will eventually be inside:** Only files whose purpose matches this folder's name.

**Why another folder is not appropriate:** Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

**Naming rules:** Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

#### VS Code method

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path repository root one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: docs.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

#### PowerShell method

### Action 18.D1.1 — Create the folder docs

---

#### Application:

Windows PowerShell or the VS Code PowerShell terminal

#### Window or panel:

VS Code integrated PowerShell terminal at the repository root

#### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

#### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

#### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

#### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

#### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.

2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop
```

### Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `New-Item -ItemType Directory -Path ".\docs" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `Directory` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

### Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

**Folder-creation decision branches****If the folder is created**

Run `Test-Path -LiteralPath ".\docs" -PathType Container` and require `True`.

**If PowerShell says the folder already exists**

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\docs" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

**If the parent path does not exist**

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

**Verify the folder**

1. Run `Test-Path ".\docs" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

**Folder introduction — scripts/**

**Exact folder name:** `scripts`

**Exact parent:** `repository root`

**Why it is needed now:** Phase 18 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

**What will eventually be inside:** Only files whose purpose matches this folder's name.

**Why another folder is not appropriate:** Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

**Naming rules:** Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

**VS Code method**

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `repository root` one level at a time.
4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: `scripts`.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

**PowerShell method****Action 18.D2.1 — Create the folder scripts**

---

**Application:**

Windows PowerShell or the VS Code PowerShell terminal

**Window or panel:**

VS Code integrated PowerShell terminal at the repository root

**Starting condition:**

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

**Current folder or location:**

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

**What you are about to do:**

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

**Why this action comes now:**

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

**Exact physical actions:**

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

**Command or code (PowerShell):**

```
New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop
```

**Where to enter it:**

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

**Plain-English translation:**

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

**What each part means:**

- **Line 1:** New-Item -ItemType Directory -Path ".\scripts" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

**Does it change anything?**

This can change files, Git state, packages, database objects, or data.

**Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

**Folder-creation decision branches****If the folder is created**

Run `Test-Path -LiteralPath ".\scripts" -PathType Container` and require `True`.

**If PowerShell says the folder already exists**

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

**If the parent path does not exist**

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

**Verify the folder**

1. Run `Test-Path ".\scripts" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

**Folder introduction — scripts/validation/**

**Exact folder name:** `validation`

**Exact parent:** `scripts`

**Why it is needed now:** Phase 18 is about to place its first responsibility-specific file here; creating it earlier would have produced an unexplained empty structure.

**What will eventually be inside:** Only files whose purpose matches this folder's name.

**Why another folder is not appropriate:** Separation keeps source SQL, transformations, tests, configuration, documentation, and generated artifacts reviewable.

**Naming rules:** Preserve lowercase/uppercase exactly as shown. Hyphens, underscores, spaces, and plural forms create different paths. This project avoids spaces in technical folder names.

**VS Code method**

1. CLICK: Open Explorer in VS Code.
2. LOOK FOR: Confirm the repository root is the top folder.
3. Expand the parent path `scripts` one level at a time.

4. RIGHT-CLICK: Right-click the immediate parent folder.
5. CLICK: **New Folder**.
6. TYPE THIS: validation.
7. PRESS: Enter.
8. LOOK FOR: The folder appears once, at the correct indentation level.

## PowerShell method

### Action 18.D3.1 — Create the folder scripts/validation

#### Application:

Windows PowerShell or the VS Code PowerShell terminal

#### Window or panel:

VS Code integrated PowerShell terminal at the repository root

#### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

#### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

#### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

#### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

#### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

#### Command or code (PowerShell):

```
New-Item -ItemType Directory -Path ".\scripts\validation" -ErrorAction Stop
```

#### Where to enter it:

VS Code integrated PowerShell terminal at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

#### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

#### What each part means:

- **Line 1:** New-Item -ItemType Directory -Path ".\scripts\validation" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; Directory is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\scripts\validation" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

**Does it change anything?**

This can change files, Git state, packages, database objects, or data.

**Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

**Folder-creation decision branches****If the folder is created**

Run `Test-Path -LiteralPath ".\scripts\validation" -PathType Container` and require `True`.

**If PowerShell says the folder already exists**

Do not delete or recreate it. Run `Get-ChildItem -LiteralPath ".\scripts\validation" -Force`, inspect its existing files, and preserve them. Continue only when the existing folder is the intended path.

**If the parent path does not exist**

Return to the parent-folder tutorial. Create and verify one parent level at a time; do not create the entire future tree in one command.

**Verify the folder**

1. Run `Test-Path ".\scripts\validation" -PathType Container`.
2. Require the output `True` before creating a child file.
3. Remember: Git does not track an empty folder by itself; the folder becomes visible in Git history when a tracked file is added.

## File introduction — docs/security\_and\_cost.md

**Exact filename:** security\_and\_cost.md

**Filename extension:** .md. In this project it identifies project documentation and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** docs relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** project documentation for Phase 18.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

### VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in docs one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: security\_and\_cost.md.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled security\_and\_cost.md and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

### PowerShell path

## Action 18.F1.1 — Create the file docs/security\_and\_cost.md from PowerShell

---

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.

5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

#### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\docs\security_and_cost.md" -ErrorAction Stop
```

#### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

#### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

#### What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\docs\security_and_cost.md" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\docs\security_and_cost.md"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

#### Does it change anything?

This can change files, Git state, packages, database objects, or data.

#### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

#### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

#### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

#### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

#### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

#### Do not continue unless:

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

#### Common mistake:

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

#### Exact recovery:

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

#### What you just accomplished:

You executed and checked one controlled operation rather than treating a long script as a black box.

## How this connects to the project:

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

## File-creation decision branches

### If the command creates the file

Run `Test-Path -LiteralPath ".\docs\security_and_cost.md" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

### If PowerShell says the file already exists

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "docs/security_and_cost.md"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

### If PowerShell says part of the path does not exist

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

## File-content construction

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under docs.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `docs/security_and_cost.md`.
3. In PowerShell at the repository root, run `Test-Path ".\docs\security_and_cost.md"` and require True.
4. Run `git status --short -- "docs/security_and_cost.md"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for docs/security\_and\_cost.md

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** Markdown

**Exact file:** `docs/security_and_cost.md`

**Purpose:** project documentation.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 18.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
Security, Configuration, and Cost Controls

Secret handling

- `.env` is local and ignored. `.env.example` contains names and safe placeholders only.
- Never commit database passwords, Databricks tokens, Power BI credentials, connection strings with secrets, or private keys.
- Use `git check-ignore .env` before the first commit.
- If a secret reaches Git, assume it is compromised: revoke/rotate it first, then remove history using an approved method. Deleting the visible line is not enough.
- Use Databricks secret management or supported cloud identities for Track B. Do not display secret values in notebook output.
- Redact logs and screenshots.

Least privilege

| Identity | Minimum learning access |
|---|---|
| Local source loader | Insert/select in source schemas; no server-admin need after setup |
| Local extractor | Read-only on source tables and watermark metadata |
| Databricks workflow | Read/write on project volume, Bronze/Silver/Gold/quality schemas only |
| Local Gold publisher | Stage/load in warehouse plus audit writes |
| Power BI/analyst | Read-only on `dw` tables or `semantic` views |

Use separate identities in a real environment. Track A may use your local Windows identity for simplicity, but document that this is not a production access model.
```

```

Development versus production configuration

- `config/dev.example.yml` is a template; create `config/dev.yml` locally and ignore it if it contains environment-specific values.
- Use environment variables for secrets.
- Keep catalog/schema/database names parameterized.
- Development can use safe full reloads; production usually needs tested incremental strategies and deployment controls.
- The destructive reset scripts contain guards. Never remove the guard in shared environments.

Synthetic PII practice

Although all identities are fictional, mask or hide names/emails in executive pages, limit detail access, and classify fields. This builds habits without using real people.

Cost-aware choices

- Generate `quick` while debugging, `small` after logic works, and `portfolio` only for a final performance demonstration.
- Free/community offerings have quota and feature limits that can change; verify the current official page before relying on them.
- Use serverless/job compute only for active tasks; avoid repeated blind retries.
- Stop local database services when you no longer need them if your computer resources are constrained.
- Import mode in Power BI is the default Track A choice; refresh intentionally.
- Track B can create charges for databases, compute, storage, egress, networking, and Power BI capacity/licensing. Set budgets/alerts before creating resources.

Secret-scanning checklist

- [] `.env` is ignored and absent from `git ls-files`.
- [] No password/token/private-key pattern appears in tracked text.
- [] Notebook outputs contain no credentials.
- [] Screenshots hide server details and account email where unnecessary.
- [] GitHub Actions uses encrypted repository/environment secrets only when needed.
- [] Public sample data is quick-scale and fictional.
- [] Connection test logs redact passwords.
- [] Any exposed credential was revoked, not merely deleted from a file.

```

## Line-by-line explanation

- **Line 1:** # Security, Configuration, and Cost Controls is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 2:** blank line used only to separate logical sections for readability.
- **Line 3:** ## Secret handling is a comment for a human reader; it normally does not change data or execute business logic.
- **Line 4:** blank line used only to separate logical sections for readability.

[Back to the Phase 18 lesson index](#)

## File introduction — scripts/validation/scan\_secrets.py

**Exact filename:** scan\_secrets.py

**Filename extension:** .py. In this project it identifies executable Python logic and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** scripts/validation relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** executable Python logic for Phase 18.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

## VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in scripts/validation one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: scan\_secrets.py.
8. PRESS: Enter.

9. LOOK FOR: A new editor tab labeled `scan_secrets.py` and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

## PowerShell path

# Action 18.F2.1 — Create the file `scripts/validation/scan_secrets.py` from PowerShell

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\scripts\validation\scan_secrets.py" -ErrorAction Stop
```

### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `New-Item` -Item Type `File` -Path `".\scripts\validation\scan_secrets.py"` -Error Action `Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\scripts\validation\scan_secrets.py"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

**Does it change anything?**

This can change files, Git state, packages, database objects, or data.

**Is it safe to rerun?**

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

**File-creation decision branches****If the command creates the file**

Run `Test-Path -LiteralPath ".\scripts\validation\scan_secrets.py" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

**If PowerShell says the file already exists**

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- "scripts/validation/scan_secrets.py"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

**If PowerShell says part of the path does not exist**

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

**File-content construction**

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.

5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use TODO(USER) where the workbook requires your own decision or verified value.

## File verification

1. In the VS Code Explorer, confirm the file appears under scripts/validation.
2. Right-click the editor tab and choose **Copy Path**; compare the ending with scripts/validation/scan\_secrets.py.
3. In PowerShell at the repository root, run Test-Path ".\scripts\validation\scan\_secrets.py" and require True.
4. Run git status --short -- "scripts/validation/scan\_secrets.py" to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for scripts/validation/scan\_secrets.py

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** Python

**Exact file:** scripts/validation/scan\_secrets.py

**Purpose:** executable Python logic.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 18.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```

[Back to the Phase 18 lesson index](#)

## File introduction — .env.example

**Exact filename:** `.env.example`

**Filename extension:** `.example`. In this project it identifies project text or configuration and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** `.` relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** project text or configuration for Phase 18.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** Yes—review carefully before Git staging.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

### VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is `SQL-Data-Warehouse-Project` and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in `.` one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: `.env.example`.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled `.env.example` and an empty file under the correct parent folder.
10. PRESS: `Ctrl+S` after adding each explained section.

### PowerShell path

## Action 18.F3.1 — Create the file .env.example from PowerShell

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root `C:\Users\User\Desktop\Northstar_Retail\SQL-Data-Warehouse-Project`. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\env.example" -ErrorAction Stop
```

### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** `New-Item -ItemType File -Path ".\env.example" -ErrorAction Stop` — `New-Item` creates a file or folder; `-ItemType` is a command option or flag; its exact behavior is defined beside the command; `File` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; `-Path` is a command option or flag; its exact behavior is defined beside the command; `".\env.example"` is a path, relative location, branch-style name, or file argument; verify every character before running it; `-ErrorAction` is a command option or flag; its exact behavior is defined beside the command; `Stop` is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

### What should happen:

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

### Expected example:

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

### What may look different:

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

### How to verify success:

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as RUN BY USER or VERIFIED BY USER. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

**File-creation decision branches****If the command creates the file**

Run `Test-Path -LiteralPath ".\env.example" -PathType Leaf`. Continue only when it returns True and the file is empty because you just created it.

**If PowerShell says the file already exists**

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- ".env.example"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

**If PowerShell says part of the path does not exist**

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

**File-content construction**

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with Ctrl+S.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

**File verification**

1. In the VS Code Explorer, confirm the file appears under ..
2. Right-click the editor tab and choose **Copy Path**; compare the ending with `.env.example`.
3. In PowerShell at the repository root, run `Test-Path ".\env.example"` and require True.
4. Run `git status --short -- ".env.example"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

**Optional reference answer for .env.example**

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** configuration text

**Exact file:** `.env.example`

**Purpose:** project text or configuration.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 18.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.

```
Copy this file to .env. Never commit .env.
Track A uses Windows Authentication for SQL Server by default.

APP_ENV=dev
LOG_LEVEL=INFO
```

```

SQLSERVER_SERVER=localhost
SQLSERVER_INSTANCE=MSSQLSERVER

## File introduction — .gitignore

**Exact filename:** .gitignore

**Filename extension:** (no extension). In this project it identifies project text or configuration and helps the correct application choose syntax highlighting or execution behavior.

**Exact parent folder:** . relative to the repository root.

**Why this file belongs there:** Files with the same responsibility are grouped so a reviewer can find configuration, source SQL, transformations, tests, documentation, and report assets without guessing.

**What the file will contain:** project text or configuration for Phase 18.

**Later dependencies:** Later phase commands, tests, GitHub Actions, Databricks tasks, warehouse loads, Power BI work, or portfolio evidence may depend on its exact path.

**Should Git track it?** Yes, unless the lesson explicitly identifies it as generated data, a local secret, a log, or a machine-specific artifact.

**Could it contain secrets?** It should not contain live passwords, tokens, connection strings, or account identifiers.

**What happens if it is missing:** The corresponding phase cannot be reproduced, validated, or explained from the repository alone.

## VS Code click path

1. CLICK: In VS Code, open **Explorer** from the left Activity Bar.
2. LOOK FOR: Confirm the top-level folder name is SQL-Data-Warehouse-Project and the status bar shows the intended Git branch.
3. CLICK: Expand each parent folder in . one level at a time.
4. If a parent folder does not exist, use the folder tutorial in this phase before creating the file.
5. RIGHT-CLICK: Right-click the immediate parent folder.
6. CLICK: Select **New File**.
7. TYPE THIS: .gitignore.
8. PRESS: Enter.
9. LOOK FOR: A new editor tab labeled .gitignore and an empty file under the correct parent folder.
10. PRESS: Ctrl+S after adding each explained section.

## PowerShell path

## Action 18.F4.1 — Create the file .gitignore from PowerShell

### Application:

Windows PowerShell or the VS Code PowerShell terminal

### Window or panel:

VS Code integrated PowerShell terminal opened at the repository root

### Starting condition:

The preceding action is verified, open work is saved, and you have not assumed that a similarly named folder, branch, server, database, catalog, schema, table, or file is the correct one.

### Current folder or location:

The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username.

### What you are about to do:

Run one explained PowerShell instruction and inspect its result before any next command is introduced.

### Why this action comes now:

The next action depends on this command's observed state or created object. Separating commands prevents an early failure from being hidden by later output.

### Exact physical actions:

1. CLICK: Bring **Windows PowerShell or the VS Code PowerShell terminal** to the front.
2. LOOK FOR: Confirm the current location matches The repository root C:\Users\User\Desktop\Northstar\_Retail\SQL-Data-Warehouse-Project. The User segment is an example; verify your real Windows username. or the more specific location stated below.
3. CLICK: Place the text cursor in the terminal, query editor, notebook cell, DAX formula bar, or GitHub field named below.
4. TYPE THIS: Enter the command exactly as shown in the code block. Do not type the prompt or expected output.
5. PRESS: Press **Enter** for a one-line terminal command, **F5/Execute** for the named database editor, or the notebook cell Run control as stated.
6. LOOK FOR: Wait until the busy indicator stops and a new prompt, result grid, cell output, or status badge appears.
7. DO NOT CONTINUE UNTIL: Compare the result with the expected shape and complete the verification action.

### Command or code (PowerShell):

```
New-Item -ItemType File -Path ".\gitignore" -ErrorAction Stop
```

### Where to enter it:

VS Code integrated PowerShell terminal opened at the repository root. Do not enter terminal commands into a source-code file and do not paste expected output back into the editor.

### Plain-English translation:

This instruction asks the selected application to perform exactly the operation named by its leading keyword, using the following names, paths, clauses, flags, and values as inputs.

### What each part means:

- **Line 1:** New-Item -ItemType File -Path ".\gitignore" -ErrorAction Stop — New-Item creates a file or folder; -ItemType is a command option or flag; its exact behavior is defined beside the command; File is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation; -Path is a command option or flag; its exact behavior is defined beside the command; ".\gitignore" is a path, relative location, branch-style name, or file argument; verify every character before running it; -ErrorAction is a command option or flag; its exact behavior is defined beside the command; Stop is a name, keyword, argument, identifier, or literal whose project-specific role is described in the surrounding explanation

### Does it change anything?

This can change files, Git state, packages, database objects, or data.

### Is it safe to rerun?

Safe to rerun only after reading the idempotency note and confirming that the same batch, file, or object will not be duplicated.

**What should happen:**

The application should finish without an unhandled error and display a result that corresponds to the command's stated purpose.

**Expected example:**

Your exact values may differ. The exact values may differ. Expect either a version/path/status line, a query result grid, or a clearly labeled completion message that matches the command purpose.

**What may look different:**

Your Windows username, installation version, server instance, database owner, generated identifier, batch timestamp, row count, Databricks interface label, Power BI ribbon position, and terminal theme can differ. A different object name, wrong branch, wrong database, missing target, unexpected duplicate, or failed quality status is not harmless.

**How to verify success:**

Run or perform the smallest independent check named in the lesson. For a path, use `Get-Location` or `Test-Path`; for Git, use `git status` and `git branch --show-current`; for SQL, run a metadata or row-count query; for Databricks, inspect the target object and cell output; for Power BI, compare a filtered DAX result to SQL.

**Do not continue unless:**

The result is visible, understandable, and recorded as `RUN BY USER` or `VERIFIED BY USER`. Displaying this workbook does not count as execution.

**Common mistake:**

The most common mistake is running the right text in the wrong application, folder, database, catalog, schema, branch, or notebook language.

**Exact recovery:**

Do not delete, reset, overwrite, or force-push. Read the first error line. Re-run the location check for this application. Confirm the current folder, branch, server/database, or Databricks catalog. Correct only the mismatched location or spelling, then retry this single command.

**What you just accomplished:**

You executed and checked one controlled operation rather than treating a long script as a black box.

**How this connects to the project:**

This verified state becomes a dependable input to the next Northstar Retail construction action.

[Back to the Phase 18 lesson index](#)

**File-creation decision branches****If the command creates the file**

Run `Test-Path -LiteralPath ".\.\.gitignore" -PathType Leaf`. Continue only when it returns `True` and the file is empty because you just created it.

**If PowerShell says the file already exists**

Do not add `-Force`, do not clear the file, and do not overwrite it. Open the existing file in VS Code, run `git status --short -- ".gitignore"`, inspect its contents and Git history, and decide whether this lesson should edit the preserved file rather than create a new one.

**If PowerShell says part of the path does not exist**

Stop. Create only the missing parent folder through the earlier folder tutorial, verify it with `Test-Path -PathType Container`, and rerun this one file command.

**File-content construction**

1. Start with the smallest header, comment, or first section shown in the phase lesson.
2. Read the purpose before typing the section.
3. Add one logical section at a time.
4. Save with `Ctrl+S`.
5. Run the syntax or content validation named in the phase.
6. Correct the first error before adding another section.
7. Use `TODO(USER)` where the workbook requires your own decision or verified value.

**File verification**

1. In the VS Code Explorer, confirm the file appears under `..`

2. Right-click the editor tab and choose **Copy Path**; compare the ending with `.gitignore`.
3. In PowerShell at the repository root, run `Test-Path ".\.\.gitignore"` and require `True`.
4. Run `git status --short -- ".gitignore"` to see only this file's Git state.
5. Run the phase-specific validator before committing.

## Optional reference answer for `.gitignore`

Attempt the file construction first. This reference is learning material, not evidence that you created or ran the file.

**Language:** text

**Exact file:** `.gitignore`

**Purpose:** project text or configuration.

**Inputs:** The requirements, configuration, source data, or upstream objects described in Phase 18.

**Expected outputs:** The file's declared objects, logs, tables, checks, or documentation when the user later runs or reads it.
